Abstract

Morphological operations play an important role in fingerprint recognition. In this paper, we examine their effect on error probabilities in a restricted statistical model.

1 Introduction

Fingerprint analysis has played an important role in biometric identification for more than a century [3] with a variety of applications ranging from border control to smartphone development. By comparing the characteristic features of two fingerprints, called minutiae, it can be determined, if it is likely, that they have originated from the same individual. Complementary to the study of matching algorithms, the usage of image preprocessing techniques to improve the performance of these matching algorithms has become a beneficial field of study. One important preprocessing step of many automated matching algorithms is the extraction of the so-called *region of interest* (ROI) of the fingerprint aiming at dividing a given fingerprint image into the ROI or foreground, that contains the features and thus the minutiae and ridges of the fingerprint, and the background, that contains no information about the fingerprint, see [5].

Automated extraction of the ROI is often achieved by the use of thresholding methods, see [8], and morphological operators, see [1, 4, 8]. While the thresholding methods provide a binarization of the image to categorize pixels into ROI and background, the use of morphological operators aims at minimizing errors such as falsely classifying a background pixel as ROI or vice versa. The construction of these morphological operators relies on prior information of the fingerprint image, such as convexity and oscillatory behaviour within the ROI.

We interpret the thresholding techniques via statistical testing. In this sense, falsely classifying a background pixel as a foreground pixel and vice versa can be seen as a type I and II error in a statistical test. The application of morphological operators is an attempt to lower the amount of the errors in this testing procedure.

The interplay of thresholding techniques with post-processing via morphological operators, incorporating prior knowledge, has, to the best of the author's knowledge, not been addressed. This thesis aims at providing a first step towards understanding this interplay by quantifying the change of the probabilities of type I and II errors through application of morphological

operators.

Our goal is the study of the improvements of the error probabilities for a specific pixel. We limit our research to a simplified model, for which we can bound the probability of a type I error after thresholding. This model assumes a rectangular region of interest with a checkerboard pattern surrounded by a constant gray background, see figure 1. We analyze the impact of morphological opening and closing, since these operators only rely on a neighbourhood of the specific pixel we are considering. The model still exhibits convexity of the ROI and an oscillatory pattern within the ROI, as in a fingerprint image.

Since we are interested in the change of the error probabilities for a specific pixel, we do not consider methods to test for the whole rectangle, but develop a test for each pixel to decide whether or not it is part of the rectangular region of interest.

The statistical model Let $m, n \in \mathbb{N}$ and $c \in \mathbb{R} \setminus \{0\}$. We assume we are given a noisy image following the statistical model

$$F(i, j) = \underbrace{c + V(i, j)}_{=: \tilde{V}(i, j)} + \varepsilon_{i, j} \quad (1)$$

for all $(i, j) \in \Omega := \{1, \dots, m\} \times \{1, \dots, n\}$. We assume, that the values of V alternate between c and $-c$ along the rows and columns of the region of interest, and call the set of all such images $\mathcal{V}_c^{m, n}$. We assume the noise terms $\varepsilon_{i, j} \sim \mathcal{N}(0, \sigma^2)$ to be i.i.d. normally distributed random variables for some $\sigma > 0$.

For visualization we use grayscale images and take $c = 127.5$. Then the values of the image \tilde{V} alternate between 0 and 255 along the region of interest, which translates to black and white in a grayscale image. This gives the region of interest of \tilde{V} a classical checkerboard pattern, see figure 1 for an example.

Notably, we make two simplifications in our statistical model. First, we assume the variance σ of the noise terms to be known beforehand. Second, we ignore the limitations of grayscale images and let the images in our model

Figure 1: Example of an image, that contains a rectangular region of interest with a checkerboard pattern.

take all values in the real numbers.

The image F is the observed data we are given. The goal is to develop a statistical test for every pixel to determine whether or not the pixel belongs to the region of interest of V and as such reconstructing the unknown V from the noisy data. The pixel (i, j) belonging to the ROI is equivalent to $\min\{\|\Delta^+ V(i, j)\|, \|\Delta^- V(i, j)\|\} \neq 0$, where Δ^+ and Δ^- denote the forward and backward discrete derivative operator, respectively. Thus, we get the null and alternative hypotheses

$$H_0(i, j) : \min\{\|\Delta^+ V(i, j)\|, \|\Delta^- V(i, j)\|\} = 0,$$

$$H_1(i, j) : \min\{\|\Delta^+ V(i, j)\|, \|\Delta^- V(i, j)\|\} \neq 0.$$

We use

$$T(i, j) := \min\{\|\Delta^+ F(i, j)\|, \|\Delta^- F(i, j)\|\}$$

as a test statistic for each pixel $(i, j) \in \Omega$. Based on the null hypotheses, we define the sets

$$\mathcal{H}_0(i, j) := \left\{ V \in \mathcal{V}_c^{m,n} \mid \min\{\|\Delta^+ V(i, j)\|, \|\Delta^- V(i, j)\|\} = 0 \right\}.$$

Then $H_0(i, j)$ is true, if and only if $V \in \mathcal{H}_0(i, j)$. In the following, we denote by $\mathbb{P}_V(\dots)$ the probability of an event given a *fixed* image V .

Let $V \in \mathcal{H}_0(i, j)$. Then we have $\|\Delta^+ V(i, j)\| = 0$ or $\|\Delta^- V(i, j)\| = 0$. Based on this fact, we define two subsets of $\mathcal{H}_0(i, j)$ by

$$\begin{aligned} \mathcal{H}_0^+(i, j) &:= \left\{ V \in \mathcal{V}_c^{m,n} \mid \|\Delta^+ V(i, j)\| = 0 \right\}, \\ \mathcal{H}_0^-(i, j) &:= \left\{ V \in \mathcal{V}_c^{m,n} \mid \|\Delta^- V(i, j)\| = 0 \right\} \end{aligned}$$

and get $\mathcal{H}_0(i, j) = \mathcal{H}_0^+(i, j) \cup \mathcal{H}_0^-(i, j)$. The union is not necessarily disjoint. For $V \in \mathcal{H}_0^+(i, j)$ we can bound the probability of a type I error by

$$\mathbb{P}_V(T(i, j) \geq t) \leq \mathbb{P}_V(\|\Delta^+ F(i, j)\| \geq t)$$

and for $V \in \mathcal{H}_0^-(i, j)$ by

$$\mathbb{P}_V(T(i, j) \geq t) \leq \mathbb{P}_V(\|\Delta^- F(i, j)\| \geq t).$$

The right hand side of both inequalities is the same function, which can be computed explicitly. Using a trial and error algorithm, we can find a threshold t_α for a given statistical significance $\alpha \in (0, 1)$, such that

$$\mathbb{P}_V(T(i, j) \geq t_\alpha) \leq \alpha$$

for every $(i, j) \in \Omega$ and $V \in \mathcal{H}_0(i, j)$.

Since this is independent of the specific V , it holds for all images V under

which the null hypothesis for the pixel (i, j) is true and thus we can bound the probability of falsely categorizing a background pixel as a foreground pixel by a given statistical significance $\alpha \in (0, 1)$.

Main results After having established our statistical testing procedure and how a suitable threshold can be computed, we aim at researching the changes of the error probabilities under morphological opening and closing. To this end, let $\mathfrak{J} \in \{0, 1\}^{m \times n}$ be a binary matrix and $\Psi \subseteq \mathbb{Z}^2$ be a *structuring element*, see [7]. We denote by $\mathfrak{J} \circ \Psi$ the opening of the binary matrix \mathfrak{J} by Ψ and by $\mathfrak{J} \bullet \Psi$ the closing of the binary matrix \mathfrak{J} by Ψ .

As the region of interest in our case is rectangular, we use a square structuring element. Using such a square structuring element yields an exponential improvement of probability of a type I error after morphological opening compared to the probability before opening is applied. Applying morphological closing after opening will worsen this probability, but only polynomially. This yields an overall improvement of the probability of a type I error, when applying morphological opening and closing. This result is formalized in the following theorem.

Theorem 1.1. *Let $m, n \in \mathbb{N}$, $c \in \mathbb{R} \setminus \{0\}$ and $\Omega = \{1, \dots, m\} \times \{1, \dots, m\}$. Assume we are given data*

$$F(i, j) = c + V(i, j) + \varepsilon_{i,j}$$

for all $(i, j) \in \Omega$, where the unknown V contains a rectangular region of interest with a checkerboard pattern and $\varepsilon_{i,j} \sim \mathcal{N}(0, \sigma^2)$ are i.i.d. normal distributed random variables for some $\sigma > 0$.

Let $\alpha \in (0, 1)$ and t_α a threshold, such that $\mathbb{P}_V(\|\Delta^+ F(i, j)\| \geq t_\alpha) \leq \alpha$ for every $V \in \mathcal{H}_0^+(i, j)$ and $\mathbb{P}_V(\|\Delta^- F(i, j)\| \geq t_\alpha) \leq \alpha$ for every $V \in \mathcal{H}_0^-(i, j)$.

Let \mathfrak{J}_α be the binary image defined by

$$\mathfrak{J}_\alpha(i, j) = \mathbb{1}_{\{T(i,j) \geq t_\alpha\}}$$

for all $(i, j) \in \Omega$.

Let $\varphi \in \mathbb{N}$ be odd. Let $\Phi_\varphi = \{-\frac{\varphi-1}{2}, -\frac{\varphi-3}{2}, \dots, \frac{\varphi-3}{2}, \frac{\varphi-1}{2}\}$ and $\Psi_\varphi = \Phi_\varphi \times \Phi_\varphi$ be a structuring element. Let $(i, j) \in \Omega$ and $V \in \mathcal{H}_0(i, j)$. Then the following inequalities hold:

$$\mathbb{P}_V((\mathfrak{I}_\alpha \circ \Psi_\varphi)(i, j) = 1) \leq \varphi \alpha^{\frac{\varphi+1}{2}} \quad (2)$$

$$\mathbb{P}_V(((\mathfrak{I}_\alpha \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 1) \leq \varphi^3 \alpha^{\frac{\varphi+1}{2}} \quad (3)$$

We are also interested in the change of the probability of a type II error, when morphological opening and closing are applied. Morphological opening increases this probability polynomially. The application of morphological closing, when applied after opening, does not lower the probability, since the pixels are not independent anymore. This is formalized in the following theorem.

Theorem 1.2. Let $m, n \in \mathbb{N}$, $c \in \mathbb{R} \setminus \{0\}$ and $\Omega = \{1, \dots, m\} \times \{1, \dots, m\}$. Assume we are given data

$$F(i, j) = c + V(i, j) + \varepsilon_{i,j}$$

for all $(i, j) \in \Omega$, where the unknown V contains a rectangular region of interest with a checkerboard pattern and $\varepsilon_{i,j} \sim \mathcal{N}(0, \sigma^2)$ are i.i.d. normal distributed random variables for some $\sigma > 0$.

Let t be a threshold, such that

$$\mathbb{P}_V(T(i, j) \leq t) \leq \beta$$

for all $V \in \mathcal{H}_1(i, j)$. Let \mathfrak{I} be the binary image defined by

$$\mathfrak{I}(i, j) = \mathbb{1}_{\{T(i,j) \geq t\}} \quad (4)$$

for all $(i, j) \in \Omega$.

Let $\varphi \in \mathbb{N}$ be odd. Let $\Phi_\varphi = \{-\frac{\varphi-1}{2}, -\frac{\varphi-3}{2}, \dots, \frac{\varphi-3}{2}, \frac{\varphi-1}{2}\}$ and $\Psi_\varphi = \Phi_\varphi \times \Phi_\varphi$ be a structuring element. Let $(i, j) \in \Omega$ and $V \in \mathcal{H}_1(i, j)$.

Denote by $\Lambda = \{\kappa_1, \dots, \kappa_2\} \times \{\lambda_1, \dots, \lambda_2\}$ the rROI contained in V . Let

$\min\{\kappa_2 - \kappa_1 + 1, \lambda_2 - \lambda_1 + 1\} \geq \varphi$. Then the following inequalities hold:

$$\mathbb{P}_V((\mathfrak{I} \circ \Psi_\varphi)(i, j) = 0) \leq \varphi^2 \beta \quad (5)$$

$$\mathbb{P}_V(((\mathfrak{I} \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 0) \leq \varphi^2 \beta \quad (6)$$

Outline of the paper In Section 2.1 we introduce definitions and notation of the aforementioned images and properties. With the introduced terminology we develop a statistical test for every pixel determining whether or not it is part of the region of interest in Section 2.2. After having established the statistical test, we proof in Section 2.3 that we can bound the probability of a type I error by a given statistical significance and analyze the probability of a type II error in the statistical test in Section 2.4. In Section 3 the two morphological operators, that we study in this paper, are introduced, along with some examples of their application. From there, we proceed to proof the main theorems of this paper in Section 4. We compare our theoretical results to simulations in Section 5 and discuss possible further research in Section 6.

2 Testing for a rectangular region of interest

2.1 Definitions

We consider a simplified model. Assume that the noise-free image V in our statistical model has a rectangular region of interest with a checkerboard pattern, cf. equation (1) and figure 1. In the following we give formal definitions of these properties.

Definition 2.1. Let $m, n \in \mathbb{N}$ and $V \in \mathbb{R}^{m \times n}$. Let $(\kappa_1, \lambda_1), (\kappa_2, \lambda_2) \in \mathbb{N}^2$ be two pairs of indices with $1 \leq \kappa_1 \leq \kappa_2 \leq m$ and $1 \leq \lambda_1 \leq \lambda_2 \leq n$, such that

$$V(i, j) \neq 0 \text{ if and only if } (i, j) \in \{\kappa_1, \dots, \kappa_2\} \times \{\lambda_1, \dots, \lambda_2\}. \quad (7)$$

We call $\Lambda = \{\kappa_1, \dots, \kappa_2\} \times \{\lambda_1, \dots, \lambda_2\}$ a *rectangular region of interest (rROI)* and say that V contains the rROI Λ .

Furthermore, we call (κ_1, λ_1) the *top left corner* and (κ_2, λ_2) the *bottom right corner* of Λ .

Definition 2.2. Let $m, n \in \mathbb{N}$ and $c \in \mathbb{R} \setminus \{0\}$. Let $V \in \mathbb{R}^{m \times n}$ be a matrix, that only takes values in the set $\{0, \pm c\}$, i.e. $V \in \{0, \pm c\}^{m \times n}$. Let V contain a rectangular region of interest Λ and let (κ_1, λ_1) be the top left corner of Λ . We say that Λ has a *checkerboard pattern*, if the equivalence

$$V(i, j) = c \Leftrightarrow i + j \equiv \kappa_1 + \lambda_1 \pmod{2} \quad (8)$$

holds for all $(i, j) \in \Lambda$.

Remark 2.3. Relation (8) implies $V(\kappa_1, \lambda_1) = c$. Furthermore, we have assumed that V only takes values in $\{0, \pm c\}$. Also, by assumption V contains a rROI, which implies $V(i, j) \neq 0$, if and only if $(i, j) \in \Lambda$. This yields

$$V(i, j) = -c \Leftrightarrow i + j \not\equiv \kappa_1 + \lambda_1 \pmod{2}$$

for all $(i, j) \in \Lambda$.

Hence, the top left corner of V takes the value c and then the values of V alternate between $+c$ and $-c$ along the rows and columns of Λ . This is similar to the classical checkerboard pattern.

Definition 2.4. Let $m, n \in \mathbb{N}$ and $c \in \mathbb{R} \setminus \{0\}$. We define $\mathcal{V}_c^{m,n}$ to be the set of all matrices, that only take values in $\{0, \pm c\}$ and that contain a rROI with a checkerboard pattern, i.e. all matrices $V \in \{0, \pm c\}^{m \times n}$, that fulfill equivalences (7) and (8) for some $1 \leq \kappa_1 \leq \kappa_2 \leq m$ and $1 \leq \lambda_1 \leq \lambda_2 \leq n$.

Remark 2.5. Any matrix $V \in \mathcal{V}_c^{m,n}$ is uniquely defined by the top left and bottom right corner of Λ . Hence, a rROI $\Lambda = \{\kappa_1, \dots, \kappa_2\} \times \{\lambda_1, \dots, \lambda_2\}$ corresponds to a unique element $V \in \mathcal{V}_c^{m,n}$, that contains the rROI Λ .

In figure 2 we see an example of such a matrix. To visualize these types of matrices, we take $c = 127.5$ and plot the grayscale image $V + c$. Thus, gray pixels represent $V = 0$, white pixels represent $V = c$ and black pixels represent $V = -c$.

The goal of the previous definitions was to formalize the objects of study of this paper: Images, that have a rectangular region of interest with a black & white checkerboard pattern surrounded by a constant gray background. We also need the forward and backward discrete derivative operator to establish our statistical test. As a reminder, we give the definition of these operators.

Definition 2.6. Let $m, n \in \mathbb{N}$ and let $V \in \mathbb{R}^{m \times n}$. Define the set of possible indices $\Omega := \{1, \dots, m\} \times \{1, \dots, n\}$. Let $(i, j) \in \Omega$. The *forward and backward discrete derivative of V evaluated at (i, j)* are defined as

$$\Delta^+ V(i, j) = \begin{pmatrix} V(i+1, j) - V(i, j) \\ V(i, j+1) - V(i, j) \end{pmatrix} \quad (9)$$

and

$$\Delta^- V(i, j) = \begin{pmatrix} V(i-1, j) - V(i, j) \\ V(i, j-1) - V(i, j) \end{pmatrix}, \quad (10)$$

respectively. To adjust to boundary issues, we use a periodic boundary condition, i.e. $V(i, j) = V(i \bmod m, j \bmod n)$ for all $(i, j) \in \mathbb{Z}^2$.

Figure 2: Example of a matrix, that contains a rROI with a checkerboard pattern. The top left corner of the rROI is (4, 3) and the bottom right corner is (8, 8). Here we have $m = n = 12$.

The following lemma shows, that the euclidean norm of these operators for matrices $V \in \mathcal{V}_c^{m,n}$ can only take specific values.

Lemma 2.7. *Let $m, n \in \mathbb{N}$ and $c \in \mathbb{R} \setminus \{0\}$. Let $V \in \mathcal{V}_c^{m,n}$. For any $(i, j) \in \Omega$ we have*

$$\|\Delta^+ V(i, j)\|, \|\Delta^- V(i, j)\| \in \{0, c, \sqrt{2}c, \sqrt{5}c, \sqrt{8}c\}. \quad (11)$$

Proof. Let $(i, j) \in \Omega$. We have assumed, that $V \in \mathcal{V}_c^{m,n}$. Thus, V only takes values in $\{0, \pm c\}$ and we obtain $\Delta^+ V(i, j), \Delta^- V(i, j) \in \{0, \pm c, \pm 2c\}^2$.

Taking the euclidean norm of all possible combinations yields

$$\|\Delta^+ V(i, j)\|, \|\Delta^- V(i, j)\| \in \{0, c, 2c, \sqrt{2}c, \sqrt{5}c, \sqrt{8}c\}.$$

We can narrow this list down even more. By assumption, V contains a rectangular region of interest Λ with a checkerboard pattern. This only allows the following combinations of $|V(i+1, j) - V(i, j)|$ and $|V(i, j+1) - V(i, j)|$:

Position of pixels $(i, j), (i+1, j), (i, j+1)$	$ V(i+1, j) - V(i, j) $	$ V(i, j+1) - V(i, j) $	$\ \Delta^+ V(i, j)\ $
$(i, j), (i+1, j), (i, j+1) \notin \Lambda$	0	0	0
$(i, j), (i+1, j) \notin \Lambda$ and $(i, j+1) \in \Lambda$	0	c	c
$(i, j), (i, j+1) \notin \Lambda$ and $(i+1, j) \in \Lambda$	c	0	c
$(i, j) \in \Lambda$ and $(i+1, j), (i, j+1) \notin \Lambda$	c	c	$\sqrt{2}c$
$(i, j), (i+1, j) \in \Lambda$ and $(i, j+1) \notin \Lambda$	$2c$	c	$\sqrt{5}c$
$(i, j), (i, j+1) \in \Lambda$ and $(i+1, j) \notin \Lambda$	c	$2c$	$\sqrt{5}c$
$(i, j), (i+1, j), (i, j+1) \in \Lambda$	$2c$	$2c$	$\sqrt{8}c$

Table 1: Possible locations of the pixels (i, j) , $(i+1, j)$, $(i, j+1)$ and the corresponding values of $|V(i+1, j) - V(i, j)|$ and $|V(i, j+1) - V(i, j)|$.

Other cases are not possible and thus $\|\Delta^+ V(i, j)\| \in \{0, c, \sqrt{2}c, \sqrt{5}c, \sqrt{8}c\}$. By a similar deduction, we also obtain $\|\Delta^- V(i, j)\| \in \{0, c, \sqrt{2}c, \sqrt{5}c, \sqrt{8}c\}$. This finishes the proof. \square

2.2 Statistical model

Our goal in this section is the development of a statistical test, that categorizes pixels as fore- or background.

Let $m, n \in \mathbb{N}$, $c \in \mathbb{R} \setminus \{0\}$ and $\Omega = \{1, \dots, m\} \times \{1, \dots, n\}$. Assume we are given noisy data

$$F(i, j) = c + V(i, j) + \varepsilon_{i,j} \quad (12)$$

for all $(i, j) \in \Omega$, where $V \in \mathcal{V}_c^{m,n}$ is unknown and $\varepsilon_{i,j} \sim \mathcal{N}(0, \sigma^2)$ are i.i.d. normal distributed random variables for some $\sigma > 0$.

Let Λ be the rectangular region of interest contained in V . We aim to find a statistical test to determine for each individual pixel whether $(i, j) \in \Lambda$ or $(i, j) \notin \Lambda$.

By the assumption, that V contains a rROI, it follows, that $V(i, j) = 0$ if and only if $(i, j) \notin \Lambda$. Let (κ_1, λ_1) and (κ_2, λ_2) be the top left and bottom right corner of Λ , respectively. Now, if $(i, j) \notin \Lambda$, it follows that $i \notin \{\kappa_1, \dots, \kappa_2\}$ or $j \notin \{\lambda_1, \dots, \lambda_2\}$. We have to distinguish four cases here:

$$\begin{aligned} i < \kappa_1 &\Rightarrow (i, j-1) \notin \Lambda \text{ and } (i-1, j) \notin \Lambda \\ &\Rightarrow V(i, j-1) = V(i-1, j) = 0 \\ j < \lambda_1 &\Rightarrow (i-1, j) \notin \Lambda \text{ and } (i, j-1) \notin \Lambda \\ &\Rightarrow V(i-1, j) = V(i, j-1) = 0 \\ i > \kappa_2 &\Rightarrow (i, j+1) \notin \Lambda \text{ and } (i+1, j) \notin \Lambda \\ &\Rightarrow V(i, j+1) = V(i+1, j) = 0 \\ j > \lambda_2 &\Rightarrow (i+1, j) \notin \Lambda \text{ and } (i, j+1) \notin \Lambda \\ &\Rightarrow V(i+1, j) = V(i, j+1) = 0 \end{aligned}$$

We see, that in the first two cases, we have $\|\Delta^- V(i, j)\| = 0$. In the latter two cases, we get $\|\Delta^+ V(i, j)\| = 0$. Thus, if $(i, j) \notin \Lambda$, it follows that $\min\{\|\Delta^+ V(i, j)\|, \|\Delta^- V(i, j)\|\} = 0$.

On the other hand, we have assumed, that Λ has a checkerboard pattern.

Thus $\|\Delta^-V(i, j)\|, \|\Delta^+V(i, j)\| \neq 0$ for $(i, j) \in \Lambda$. This yields the equivalence

$$(i, j) \notin \Lambda \Leftrightarrow \min\{\|\Delta^+V(i, j)\|, \|\Delta^-V(i, j)\|\} = 0.$$

Since our goal is to test for $(i, j) \in \Lambda$, we define a null hypothesis for each individual pixel:

$$H_0(i, j) : \min\{\|\Delta^+V(i, j)\|, \|\Delta^-V(i, j)\|\} = 0$$

We do not know the actual values of V , which makes Δ^+V and Δ^-V non-observable. Since we are given noisy data, we use this noisy data for our test statistic and test for each individual pixel (i, j) the null hypothesis

$$H_0(i, j) : \min\{\|\Delta^+V(i, j)\|, \|\Delta^-V(i, j)\|\} = 0 \quad (13)$$

against the alternative hypothesis

$$H_1(i, j) : \min\{\|\Delta^+V(i, j)\|, \|\Delta^-V(i, j)\|\} \neq 0 \quad (14)$$

using the test statistic

$$T(i, j) := \min\{\|\Delta^+F(i, j)\|, \|\Delta^-F(i, j)\|\}. \quad (15)$$

The pixels then can be categorized by rejecting the null hypothesis, i.e. classifying the pixel (i, j) as foreground, if $T(i, j) \geq t$ for some threshold $t \in \mathbb{R}^+$. How the threshold should be chosen will be examined in Section 2.3.

For convenience, we want to define some subsets of $\mathcal{V}_c^{m,n}$. For every $(i, j) \in \Omega$ we define the set of images, for which the null hypothesis $H_0(i, j)$ is true as

$$\mathcal{H}_0(i, j) := \left\{ V \in \mathcal{V}_c^{m,n} \mid \min\{\|\Delta^+V(i, j)\|, \|\Delta^-V(i, j)\|\} = 0 \right\}. \quad (16)$$

Then $H_0(i, j)$ is true, if and only if $V \in \mathcal{H}_0(i, j)$. Furthermore, we define two subsets of this set as

$$\mathcal{H}_0^+(i, j) := \left\{ V \in \mathcal{V}_c^{m,n} \mid \|\Delta^+V(i, j)\| = 0 \right\}, \quad (17)$$

$$\mathcal{H}_0^-(i, j) := \left\{ V \in \mathcal{V}_c^{m,n} \mid \|\Delta^- V(i, j)\| = 0 \right\}. \quad (18)$$

Then $\mathcal{H}_0(i, j) = \mathcal{H}_0^+(i, j) \cup \mathcal{H}_0^-(i, j)$, where the union is not necessarily disjoint.

2.3 Bound for the probability of a type I error

Having established our hypotheses and test statistic, we want to examine the choice of the threshold $t \in \mathbb{R}^+$ in the testing procedure. We reject the null hypothesis, if $T(i, j) \geq t$ for some threshold $t \in \mathbb{R}^+$. We want to choose t such, that the probability of falsely classifying a background pixel as foreground is bounded from above by a given statistical significance $\alpha \in (0, 1)$. Such a threshold will be denoted as t_α .

As a reminder, we use the notation $\mathbb{P}_V(\dots)$ for the probability of an event for some *fixed* image V . This will allow us to analyze the probabilities of falsely categorizing a pixel. Using this notation, we want to find a threshold t_α , such that $\mathbb{P}_V(T(i, j) \geq t_\alpha) \leq \alpha$ for every $V \in \mathcal{H}_0(i, j)$. A first step towards finding such a threshold is the following lemma.

Lemma 2.8. *Let $(i, j) \in \Omega$ and $t \in \mathbb{R}^+$. Assume that F follows the statistical model given in (12) and let $T(i, j)$ be defined as in (15). Let $V \in \mathcal{V}_c^{m,n}$. Then*

$$\mathbb{P}_V(T(i, j) \geq t) \leq \min \left\{ \mathbb{P}_V(\|\Delta^+ F(i, j)\| \geq t), \mathbb{P}_V(\|\Delta^- F(i, j)\| \geq t) \right\}. \quad (19)$$

Proof. Let $t \in \mathbb{R}^+$. We have

$$\begin{aligned} \mathbb{P}_V(T(i, j) \geq t) &= \mathbb{P}_V(\min\{\|\Delta^+ F(i, j)\|, \|\Delta^- F(i, j)\|\} \geq t) \\ &= \mathbb{P}_V(\{\|\Delta^+ F(i, j)\| \geq t\} \cap \{\|\Delta^- F(i, j)\| \geq t\}) \\ &\leq \mathbb{P}_V(\|\Delta^+ F(i, j)\| \geq t). \end{aligned}$$

Analogously, we obtain

$$\mathbb{P}_V(T(i, j) \geq t) \leq \mathbb{P}_V(\|\Delta^- F(i, j)\| \geq t).$$

Combining these two inequalities yields the result and thus finishes the proof of the lemma. \square

The second step is given in the following theorem, where we calculate the cumulative distribution functions of $\mathbb{P}_V(\|\Delta^+ F(i, j)\| \leq t)$ for $V \in \mathcal{H}_0^+(i, j)$ and $\mathbb{P}_V(\|\Delta^- F(i, j)\| \leq t)$ for $V \in \mathcal{H}_0^-(i, j)$, which turn out to be the same.

Theorem 2.9. *Let $(i, j) \in \Omega$ and $t \in \mathbb{R}^+$. Assume that F follows the statistical model given in (12). Let $V_1 \in \mathcal{H}_0^+(i, j)$ and $V_2 \in \mathcal{H}_0^-(i, j)$. Then*

$$\mathbb{P}_{V_1}(\|\Delta^+ F(i, j)\| \leq t) = p_\sigma(t) = \mathbb{P}_{V_2}(\|\Delta^- F(i, j)\| \leq t) \quad (20)$$

where

$$\begin{aligned} p_\sigma(t) := & \frac{1}{\sqrt{3}} \left(\frac{3}{2} - \frac{3}{2} \exp\left(-\frac{t^2}{3\sigma^2}\right) I_0\left(\frac{t^2}{6\sigma^2}\right) \right) - \sqrt{3} \\ & - \frac{2 - \sqrt{3}}{2} Q_1\left(\frac{2 - \sqrt{3}}{6} \sqrt{\frac{t}{\sigma}}, \frac{2 + \sqrt{3}}{6} \sqrt{\frac{t}{\sigma}}\right) \\ & + \frac{2 + \sqrt{3}}{2} Q_1\left(\frac{2 + \sqrt{3}}{6} \sqrt{\frac{t}{\sigma}}, \frac{2 - \sqrt{3}}{6} \sqrt{\frac{t}{\sigma}}\right) \end{aligned} \quad (21)$$

with I_0 being the modified Bessel function of the first kind and Q_M denoting the Marcum Q -function.

Proof. We start by proving the first equality of equation (20). By assumption, $V_1 \in \mathcal{H}_0^+(i, j)$ and thus $\|\Delta^+ V_1(i, j)\| = 0$. By definition of Δ^+ we get the equivalence

$$\|\Delta^+ V_1(i, j)\| = 0 \Leftrightarrow V_1(i + 1, j) - V_1(i, j) = V_1(i, j + 1) - V_1(i, j) = 0.$$

We write out the term $\mathbb{P}_{V_1}(\|\Delta^+ F(i, j)\| \leq t)$, which we call $q(t)$, and use the equivalence above to get

$$\begin{aligned} q(t) &:= \mathbb{P}_{V_1}(\|\Delta^+ F(i, j)\| \leq t) \\ &= \mathbb{P}_{V_1}\left((c + V_1(i + 1, j) + \varepsilon_{i+1,j} - c - V_1(i, j) - \varepsilon_{i,j})^2 \right. \\ &\quad \left. + (c + V_1(i, j + 1) + \varepsilon_{i,j+1} - c - V_1(i, j) - \varepsilon_{i,j})^2 \leq t^2\right) \\ &= \mathbb{P}_{V_1}\left((\varepsilon_{i+1,j} - \varepsilon_{i,j})^2 + (\varepsilon_{i,j+1} - \varepsilon_{i,j})^2 \leq t^2\right) \\ &= \mathbb{P}\left((\varepsilon_{i+1,j} - \varepsilon_{i,j})^2 + (\varepsilon_{i,j+1} - \varepsilon_{i,j})^2 \leq t^2\right) \end{aligned}$$

where we dropped the index V_1 , since the probability does no longer depend on V_1 .

Assuming the common term $\varepsilon_{i,j}$ to be constant and by defining

$$\begin{aligned} X_1 &= \varepsilon_{i+1,j} - \varepsilon_{i,j} \sim \mathcal{N}(-\varepsilon_{i,j}, \sigma^2) \\ X_2 &= \varepsilon_{i,j+1} - \varepsilon_{i,j} \sim \mathcal{N}(-\varepsilon_{i,j}, \sigma^2) \end{aligned}$$

we obtain

$$q(t) = \mathbb{P} \left(\sqrt{\left(\frac{X_1}{\sigma}\right)^2 + \left(\frac{X_2}{\sigma}\right)^2} \leq \frac{t}{\sigma} \right).$$

This shows, that the square root inside has a non-central Chi distribution with two degrees of freedom and non-centrality parameter

$$\lambda = \sqrt{\left(\frac{-\varepsilon_{i,j}}{\sigma}\right)^2 + \left(\frac{-\varepsilon_{i,j}}{\sigma}\right)^2} = \frac{\sqrt{2}|\varepsilon_{i,j}|}{\sigma}$$

and hence

$$\sqrt{\left(\frac{X_1}{\sigma}\right)^2 + \left(\frac{X_2}{\sigma}\right)^2} \sim \chi_2 \left(\frac{\sqrt{2}|\varepsilon_{i,j}|}{\sigma} \right).$$

Up until this point we assumed $\varepsilon_{i,j}$ to be constant, but it is a normal distributed random variable with zero mean and standard deviation σ . Thus, we have a compound probability distribution:

$$\begin{aligned} q(t) &= \mathbb{P} \left(\sqrt{\left(\frac{X_1}{\sigma}\right)^2 + \left(\frac{X_2}{\sigma}\right)^2} \leq \frac{t}{\sigma} \right) \\ &= \int_0^{\frac{t}{\sigma}} \int_0^\infty \underbrace{x \exp \left(-\frac{x^2}{2} - \frac{\eta^2}{\sigma^2} \right) I_0 \left(\frac{\sqrt{2}\eta}{\sigma} x \right)}_{\text{pdf of } \chi_2 \left(\frac{\sqrt{2}\eta}{\sigma} \right) \text{ for fixed } \eta} \underbrace{\frac{2}{\sqrt{2\pi\sigma^2}} \exp \left(-\frac{\eta^2}{2\sigma^2} \right)}_{\text{pdf of absolute value of } \mathcal{N}(0, \sigma^2)} d\eta dx \\ &= \frac{2}{\sqrt{2\pi\sigma^2}} \int_0^{\frac{t}{\sigma}} x \exp \left(-\frac{x^2}{2} \right) \int_0^\infty \exp \left(-\frac{3}{2\sigma^2} \eta^2 \right) I_0 \left(\frac{\sqrt{2}x}{\sigma} \eta \right) d\eta dx \end{aligned}$$

where I_0 is the modified Bessel function of the first kind. We can solve the inner integral first. For $\text{Re } \nu > -1$, $\text{Re } \alpha > 0$ the following equality holds.²

$$\int_0^\infty \exp(-\alpha x^2) I_\nu(\beta x) dx = \frac{\sqrt{\pi}}{2\sqrt{\alpha}} \exp \left(\frac{\beta^2}{8\alpha} \right) I_{\frac{1}{2}\nu} \left(\frac{\beta^2}{8\alpha} \right) \quad (22)$$

In our case, we have $\nu = 0$, $\alpha = \frac{3}{2\sigma^2}$ and $\beta = \frac{\sqrt{2}x}{\sigma}$, which yields

$$\begin{aligned} \int_0^\infty \exp\left(-\frac{3}{2\sigma^2}\eta^2\right) I_0\left(\frac{\sqrt{2}x}{\sigma}\eta\right) d\eta &= \frac{\sqrt{\pi}}{2\sqrt{\frac{3}{2\sigma^2}}} \exp\left(\frac{\frac{2x^2}{\sigma^2}}{8\frac{3}{2\sigma^2}}\right) I_0\left(\frac{\frac{2x^2}{\sigma^2}}{8\frac{3}{2\sigma^2}}\right) \\ &= \frac{\sqrt{\pi}\sigma}{\sqrt{6}} \exp\left(\frac{x^2}{6}\right) I_0\left(\frac{x^2}{6}\right). \end{aligned}$$

Plugging this in, we obtain

$$\begin{aligned} q(t) &= \frac{2}{\sqrt{2\pi\sigma^2}} \int_0^{\frac{t}{\sigma}} x \exp\left(-\frac{x^2}{2}\right) \frac{\sqrt{\pi}\sigma}{\sqrt{6}} \exp\left(\frac{x^2}{6}\right) I_0\left(\frac{x^2}{6}\right) dx \\ &= \frac{1}{\sqrt{3}} \int_0^{\frac{t}{\sigma}} x \exp\left(-\frac{x^2}{2}\right) \exp\left(\frac{x^2}{6}\right) I_0\left(\frac{x^2}{6}\right) dx \\ &= \frac{1}{\sqrt{3}} \int_0^{\frac{t}{\sigma}} x \exp\left(-\frac{x^2}{3}\right) I_0\left(\frac{x^2}{6}\right) dx. \end{aligned}$$

To proceed, we need to integrate by parts to replace the modified Bessel function I_0 with order zero by a modified Bessel function I_1 with order one.

$$\begin{aligned} q(t) &= \frac{1}{\sqrt{3}} \left[-\frac{3}{2} \exp\left(-\frac{x^2}{3}\right) I_0\left(\frac{x^2}{6}\right) \right]_0^{\frac{t}{\sigma}} + \frac{1}{2\sqrt{3}} \int_0^{\frac{t}{\sigma}} \exp\left(-\frac{x^2}{3}\right) x I_1\left(\frac{x^2}{6}\right) dx \\ &= \frac{1}{\sqrt{3}} \left(\frac{3}{2} - \frac{3}{2} \exp\left(-\frac{t^2}{3\sigma^2}\right) I_0\left(\frac{t^2}{6\sigma^2}\right) \right) + \frac{1}{2\sqrt{3}} \int_0^{\frac{t}{\sigma}} \exp\left(-\frac{x^2}{3}\right) x I_1\left(\frac{x^2}{6}\right) dx \end{aligned}$$

In the next step we substitute $y = x^2$ in the remaining integral, which leaves us with

$$q(t) = \frac{1}{\sqrt{3}} \left(\frac{3}{2} - \frac{3}{2} \exp\left(-\frac{t^2}{3\sigma^2}\right) I_0\left(\frac{t^2}{6\sigma^2}\right) \right) + \frac{1}{4\sqrt{3}} \int_0^{\frac{t}{\sigma}} \exp\left(-\frac{y}{3}\right) I_1\left(\frac{y}{6}\right) dy.$$

We want to solve the remaining integral. Let $p \neq b$ and $s = \sqrt{p^2 - b^2}$, $u = \sqrt{a(p - s)}$ and $v = \sqrt{a(p + s)}$. Then⁶

$$\int_0^a \exp(-px) I_M(bx) dx = \frac{1}{sb^M} \left((p - s)^M (1 - Q_M(u, v)) - (p + s)^M (1 - Q_M(v, u)) \right) \quad (23)$$

where Q_M denotes the Marcum Q -function. The Marcum Q -function is only

defined for $M \geq 1$, which made the integration by parts necessary. Applying this equation with $M = 1$ to the integral yields

$$\begin{aligned} \int_0^{\frac{t}{\sigma}} \exp\left(-\frac{y}{3}\right) I_1\left(\frac{y}{6}\right) dy &= \frac{1}{\frac{1}{2\sqrt{3}}\frac{1}{6}} \frac{2-\sqrt{3}}{6} \left(1 - Q_1\left(\frac{2-\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}, \frac{2+\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}\right)\right) \\ &\quad - \frac{1}{\frac{1}{2\sqrt{3}}\frac{1}{6}} \frac{2+\sqrt{3}}{6} \left(1 - Q_1\left(\frac{2+\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}, \frac{2-\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}\right)\right) \\ &= 2\sqrt{3}(2-\sqrt{3}) \left(1 - Q_1\left(\frac{2-\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}, \frac{2+\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}\right)\right) \\ &\quad - 2\sqrt{3}(2+\sqrt{3}) \left(1 - Q_1\left(\frac{2+\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}, \frac{2-\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}\right)\right). \end{aligned}$$

Plugging this in, we obtain the final result

$$\begin{aligned} q(t) &= \frac{1}{\sqrt{3}} \left(\frac{3}{2} - \frac{3}{2} \exp\left(-\frac{t^2}{3\sigma^2}\right) I_0\left(\frac{t^2}{6\sigma^2}\right)\right) + \frac{1}{4\sqrt{3}} \int_0^{\frac{t}{\sigma}} \exp\left(-\frac{y}{3}\right) I_1\left(\frac{y}{6}\right) dy \\ &= \frac{1}{\sqrt{3}} \left(\frac{3}{2} - \frac{3}{2} \exp\left(-\frac{t^2}{3\sigma^2}\right) I_0\left(\frac{t^2}{6\sigma^2}\right)\right) \\ &\quad + \frac{2\sqrt{3}}{4\sqrt{3}}(2-\sqrt{3}) \left(1 - Q_1\left(\frac{2-\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}, \frac{2+\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}\right)\right) \\ &\quad - \frac{2\sqrt{3}}{4\sqrt{3}}(2+\sqrt{3}) \left(1 - Q_1\left(\frac{2+\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}, \frac{2-\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}\right)\right) \\ &= \frac{1}{\sqrt{3}} \left(\frac{3}{2} - \frac{3}{2} \exp\left(-\frac{t^2}{3\sigma^2}\right) I_0\left(\frac{t^2}{6\sigma^2}\right)\right) - \sqrt{3} \\ &\quad - \frac{2-\sqrt{3}}{2} Q_1\left(\frac{2-\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}, \frac{2+\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}\right) \\ &\quad + \frac{2+\sqrt{3}}{2} Q_1\left(\frac{2+\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}, \frac{2-\sqrt{3}}{6}\sqrt{\frac{t}{\sigma}}\right) \\ &= p_\sigma(t). \end{aligned}$$

This finishes the proof of the first equality of equation (21). Analogously, we can proof $\mathbb{P}_{V_2}(\|\Delta^- F(i, j)\| \leq t) = p_\sigma(t)$. This proves the second equality and thus finishes the proof of Theorem 2.9. \square

Corollary 2.10. *Let $(i, j) \in \Omega$ and $t \in \mathbb{R}^+$. Assume that F follows the statistical model given in (12) and let $T(i, j)$ be defined as in (15). Then*

$$\mathbb{P}_V(T(i, j) \geq t) \leq 1 - p_\sigma(t) \quad (24)$$

for every $V \in \mathcal{H}_0(i, j)$.

Proof. Since $V \in \mathcal{H}_0(i, j)$, we have $V \in \mathcal{H}_0^+(i, j)$ or $V \in \mathcal{H}_0^-(i, j)$. In the first case, by Lemma 2.8 and Theorem 2.9 we have

$$\begin{aligned} \mathbb{P}_V(T(i, j) \geq t) &\leq \min \left\{ \mathbb{P}_V(\|\Delta^+ F(i, j)\| \geq t), \mathbb{P}_V(\|\Delta^- F(i, j)\| \geq t) \right\} \\ &\leq \mathbb{P}_V(\|\Delta^+ F(i, j)\| \geq t) \\ &= 1 - p_\sigma(t). \end{aligned}$$

The second case is proven analogously. \square

Let $\alpha \in (0, 1)$ be given. Inequality (24) shows, that if we find a threshold t_α , such that $1 - p_\sigma(t_\alpha) \leq \alpha$, we have

$$\mathbb{P}_V(T(i, j) \geq t_\alpha) \leq 1 - p_\sigma(t_\alpha) \leq \alpha \quad (25)$$

for all $V \in \mathcal{H}_0(i, j)$. Thus, using such a threshold for our testing procedure bounds the probability of a type I error below a given statistical significance α . Since the function $p_\sigma(t)$ does not depend on V , the threshold is independent of V .

Since finding inverse functions of the modified Bessel function of the first kind I_ν and of the Marcum Q -function Q_M is complicated, there is no easy way to compute an inverse function of $p_\sigma(t)$. Thus, we cannot provide a closed form to calculate the threshold, but we can compute a threshold t_α numerically with a trial and error algorithm.

To this end, we note, that $p_\sigma(t_\alpha \cdot \sigma) = p_1(t_\alpha)$. Hence, it is sufficient to calculate a threshold t_α for $\sigma = 1$. We will give a pseudocode here. A *MATLAB* implementation of this pseudocode can be found in the appendix. In figure 3 the cumulative distribution function $p_1(t)$ is plotted. For $\alpha = 0.05$ and

$\alpha = 0.01$ the thresholds have been numerically computed.

Algorithm 1: Computation of a threshold for a given statistical significance

Input: $\alpha \in (0, 1)$

Output: t_α and α_{real} , s.t. $p_1(t_\alpha) = 1 - \alpha_{real} \geq 1 - \alpha$

```

1  $t_\alpha = 0$ ;
2  $t_{inc} = 0.0001$ ;
3 while  $p_1(t_\alpha) < 1 - \alpha$  do
4    $t_\alpha + t_{inc}$ ;
5    $\alpha_{real} = 1 - p_1(t_\alpha)$ ;
6 end while
```

Figure 3: Plot of the cumulative distribution function $p_1(t)$. The numerically computed thresholds $t_{0.05} = 3.2555$ and $t_{0.01} = 4.2792$ are marked.

2.4 Analysis of the probability of a type II error

Through inequality (24) we have found a way to bound the probability of falsely classifying a background pixel as a foreground pixel below a given statistical significance. Such an error is called a type I error. We choose the threshold in the testing procedure, such that the probability of a type I error is below a given statistical significance α . Falsely classifying a foreground pixel as a background pixel is called a type II error. Since the probability of a type II error is not bounded by a given value, we are interested in upper and lower bounds for it.

To this end, we define subsets of $\mathcal{V}_c^{m,n}$. For every $(i, j) \in \Omega$ we define the set of images, for which the alternative hypothesis $H_1(i, j)$ is true as

$$\mathcal{H}_1(i, j) := \left\{ V \in \mathcal{V}_c^{m,n} \mid \min\{\|\Delta^+ V(i, j)\|, \|\Delta^- V(i, j)\|\} \neq 0 \right\}. \quad (26)$$

A first step towards bounds for the probability of a type II error is achieved in the following lemma.

Theorem 2.11. *Let $(i, j) \in \Omega$ and $t \in \mathbb{R}^+$. Assume that F follows the statistical model given (12) and let $T(i, j)$ and $H_1(i, j)$ be defined as in (15) and (14). Let $V, V_1, V_2 \in \mathcal{H}_1(i, j)$. Assume V_1 is such, that $\|\Delta^+ V_1(i, j)\| = \sqrt{2}c$ and V_2 such, that $\|\Delta^+ V_2(i, j)\| = \sqrt{8}c$. Then the following inequalities hold:*

$$\mathbb{P}_V(T(i, j) \leq t) \leq 2 \cdot \mathbb{P}_{V_1}(\|\Delta^+ F(i, j)\| \leq t) \quad (27)$$

$$\mathbb{P}_V(T(i, j) \leq t) \geq \mathbb{P}_{V_2}(\|\Delta^+ F(i, j)\| \leq t) \quad (28)$$

Proof. By assumption $V \in \mathcal{H}_1(i, j) \subseteq \mathcal{V}_c^{m,n}$. In Lemma 2.7 we showed, that

$$\|\Delta^+ V(i, j)\|, \|\Delta^- V(i, j)\| \in \{0, c, \sqrt{2}c, \sqrt{5}c, \sqrt{8}c\}.$$

By design of our statistical test, if $H_1(i, j)$ is true, then $(i, j) \in \Lambda$. As can be seen from Table 1 in the proof of Lemma 2.7, $(i, j) \in \Lambda$ implies

$$\|\Delta^+ V(i, j)\|, \|\Delta^- V(i, j)\| \in \{\sqrt{2}c, \sqrt{5}c, \sqrt{8}c\}.$$

Hence, we can rewrite the set $\mathcal{H}_1(i, j)$ as

$$\mathcal{H}_1(i, j) = \left\{ V \in \mathcal{V}_c^{m,n} \mid \|\Delta^+ V(i, j)\|, \|\Delta^- V(i, j)\| \in \{\sqrt{2}c, \sqrt{5}c, \sqrt{8}c\} \right\}.$$

Using this knowledge, we can start bounding the probability of a type II error in our testing procedure, which we call β , from above by

$$\begin{aligned} \beta(t) &:= \mathbb{P}_V (T(i, j) \leq t) \\ &= \mathbb{P}_V \left(\min \left\{ \|\Delta^+ F(i, j)\|, \|\Delta^- F(i, j)\| \right\} \leq t \right) \\ &= \mathbb{P}_V \left(\left\{ \|\Delta^+ F(i, j)\| \leq t \right\} \cup \left\{ \|\Delta^- F(i, j)\| \leq t \right\} \right) \\ &\leq \mathbb{P}_V \left(\|\Delta^+ F(i, j)\| \leq t \right) + \mathbb{P}_V \left(\|\Delta^- F(i, j)\| \leq t \right). \end{aligned}$$

This upper bound depends on the actual value of $\|\Delta^+ V(i, j)\|$, which is unknown. In both terms we take a $V^* \in \mathcal{H}_1(i, j)$ that maximizes the probability and obtain

$$\begin{aligned} \beta(t) &\leq \max_{V^* \in \mathcal{H}_1(i, j)} \mathbb{P}_{V^*} \left(\|\Delta^+ F(i, j)\| \leq t \right) + \max_{V^* \in \mathcal{H}_1(i, j)} \mathbb{P}_{V^*} \left(\|\Delta^- F(i, j)\| \leq t \right) \\ &= 2 \cdot \max_{V^* \in \mathcal{H}_1(i, j)} \mathbb{P}_{V^*} \left(\|\Delta^+ F(i, j)\| \leq t \right) \end{aligned}$$

where we used the equality

$$\max_{V^* \in \mathcal{H}_1(i, j)} \mathbb{P}_{V^*} \left(\|\Delta^+ F(i, j)\| \leq t \right) = \max_{V^* \in \mathcal{H}_1(i, j)} \mathbb{P}_{V^*} \left(\|\Delta^- F(i, j)\| \leq t \right).$$

The maximum is attained for any $V^* \in \mathcal{H}_1(i, j)$ with $\|\Delta^+ V^*(i, j)\| = \sqrt{2}c$. One such V^* is V_1 and thus we get

$$\begin{aligned} \beta(t) &\leq 2 \cdot \max_{V^* \in \mathcal{H}_1(i, j)} \mathbb{P}_{V^*} \left(\|\Delta^+ F(i, j)\| \leq t \right) \\ &= 2 \cdot \mathbb{P}_{V_1} \left(\|\Delta^+ F(i, j)\| \leq t \right) \end{aligned}$$

which proves inequality (27).

Using similar techniques, we can also get a lower bound for the probability

of a type II error. We start with

$$\begin{aligned}\beta(t) &= \mathbb{P}_V (T(i, j) \leq t) \\ &= \mathbb{P}_V \left(\min\{\|\Delta^+ F(i, j)\|, \|\Delta^- F(i, j)\|\} \leq t \right) \\ &\geq \mathbb{P}_V \left(\|\Delta^+ F(i, j)\| \leq t \right).\end{aligned}$$

Again, this lower bound is not fully determined and we bound this further by

$$\begin{aligned}\beta(t) &\geq \mathbb{P}_V \left(\|\Delta^+ F(i, j)\| \leq t \right) \\ &\geq \min_{V^* \in \mathcal{H}_1(i, j)} \mathbb{P}_{V^*} \left(\|\Delta^+ F(i, j)\| \leq t \right).\end{aligned}$$

The minimum is attained for any $V^* \in \mathcal{H}_1(i, j)$ with $\|\Delta^+ V^*(i, j)\| = \sqrt{8}c$. One such V^* is V_2 and we obtain

$$\begin{aligned}\beta(t) &\geq \min_{V^* \in \mathcal{H}_1(i, j)} \mathbb{P}_{V^*} \left(\|\Delta^+ F(i, j)\| \leq t \right) \\ &= \mathbb{P}_{V_2} \left(\|\Delta^+ F_2(i, j)\| \leq t \right)\end{aligned}$$

which proves inequality (28) and finishes the proof. \square

This result is the equivalent to Lemma 2.8 for the probability of a type II error. We would like to find an equivalent result to Theorem 2.9 to write these bounds in terms of well-known functions like we did in equation (21). This would require more generalized versions of equalities (22) and (23), which, to the best of the author's knowledge, are not known.

We can write down the compound probability distribution of the upper and lower bound from Theorem 2.11. The results are given in the following theorem.

Theorem 2.12. *Let $(i, j) \in \Omega$ and $t \in \mathbb{R}^+$. Assume that F follows the statistical model given (12) and let $T(i, j)$ and $H_1(i, j)$ be defined as in (15) and (14). Let $V_1, V_2 \in \mathcal{H}_1(i, j)$. Assume V_1 is such, that $\|\Delta^+ V_1(i, j)\| = \sqrt{2}c$*

and V_2 such, that $\|\Delta^+ V_2(i, j)\| = \sqrt{8}c$. Then the following equalities hold:

$$\begin{aligned} & \mathbb{P}_{V_1} \left(\|\Delta^+ F(i, j)\| \leq t \right) \\ &= \frac{1}{\sqrt{2\pi\sigma^2}} \int_0^{\frac{t}{\sigma}} x \exp \left(-\frac{x^2}{2} \right) \int_{-\infty}^{\infty} \exp \left(-\frac{(c-\eta)^2}{\sigma^2} - \frac{\eta^2}{2\sigma^2} \right) I_0 \left(\frac{\sqrt{2}x}{\sigma} (c-\eta) \right) d\eta dx \end{aligned} \quad (29)$$

$$\begin{aligned} & \mathbb{P}_{V_2} \left(\|\Delta^+ F(i, j)\| \leq t \right) \\ &= \frac{1}{\sqrt{2\pi\sigma^2}} \int_0^{\frac{t}{\sigma}} x \exp \left(-\frac{x^2}{2} \right) \int_{-\infty}^{\infty} \exp \left(-\frac{(2c-\eta)^2}{\sigma^2} - \frac{\eta^2}{2\sigma^2} \right) I_0 \left(\frac{\sqrt{2}x}{\sigma} (2c-\eta) \right) d\eta dx \end{aligned} \quad (30)$$

Proof. From the analysis of possible combinations of $|V(i+1, j) - V(i, j)|$ and $|V(i, j+1) - V(i, j)|$ in table 1 we can deduce the equivalences

$$\begin{aligned} |V(i+1, j) - V(i, j)| &= |V(i, j+1) - V(i, j)| = c \Leftrightarrow \|\Delta^+ V(i, j)\| = \sqrt{2}c, \\ |V(i+1, j) - V(i, j)| &= |V(i, j+1) - V(i, j)| = 2c \Leftrightarrow \|\Delta^+ V(i, j)\| = \sqrt{8}c. \end{aligned}$$

We proceed as in the proof of Theorem 2.9. We have

$$\begin{aligned} & \mathbb{P}_{V_1} \left(\|\Delta^+ F(i, j)\| \leq t \right) \\ &= \mathbb{P}_{V_1} \left((c + V_1(i+1, j) + \varepsilon_{i+1, j} - c - V_1(i, j) - \varepsilon_{i, j})^2 \right. \\ &\quad \left. + (c + V_1(i, j+1) + \varepsilon_{i, j+1} - c - V_1(i, j) - \varepsilon_{i, j})^2 \leq t^2 \right) \\ &= \mathbb{P}_{V_1} \left((V_1(i+1, j) - V_1(i, j) + \varepsilon_{i+1, j} - \varepsilon_{i, j})^2 \right. \\ &\quad \left. + (V_1(i, j+1) - V_1(i, j) + \varepsilon_{i, j+1} - \varepsilon_{i, j})^2 \leq t^2 \right). \end{aligned}$$

We define the following random variables

$$\begin{aligned} \xi_1 &= V_1(i+1, j) - V_1(i, j) - \varepsilon_{i, j} \sim \mathcal{N} \left(V_1(i+1, j) - V_1(i, j), \sigma^2 \right), \\ \xi_2 &= V_1(i, j+1) - V_1(i, j) - \varepsilon_{i, j} \sim \mathcal{N} \left(V_1(i, j+1) - V_1(i, j), \sigma^2 \right), \\ X_1 &= \xi_1 + \varepsilon_{i+1, j} \sim \mathcal{N} \left(\xi_1, \sigma^2 \right), \\ X_2 &= \xi_2 + \varepsilon_{i, j+1} \sim \mathcal{N} \left(\xi_2, \sigma^2 \right) \end{aligned}$$

and obtain

$$\mathbb{P}_{V_1} \left(\|\Delta^+ F(i, j)\| \leq t \right) = \mathbb{P}_{V_1} \left(\sqrt{\left(\frac{X_1}{\sigma}\right)^2 + \left(\frac{X_2}{\sigma}\right)^2} \leq \frac{t}{\sigma} \right).$$

Thus, we see, that the square root inside has a non-central Chi distribution with two degrees of freedom. We have assumed, that $\|\Delta^+ V_1(i, j)\| = \sqrt{2}c$. As we have seen, this is equivalent to

$$|V_1(i+1, j) - V_1(i, j)| = |V_1(i, j+1) - V_1(i, j)| = c.$$

We can replace ξ_1 or ξ_2 by $-\xi_1$ or $-\xi_2$, respectively, without changing the probability. Thus, we can assume without loss of generality

$$V_1(i+1, j) - V_1(i, j) = V_1(i, j+1) - V_1(i, j) = c.$$

Assuming $\varepsilon_{i,j}$ to be constant, this non-central Chi distribution has non-centrality parameter

$$\begin{aligned} \lambda &= \sqrt{\left(\frac{V_1(i+1, j) - V_1(i, j) - \varepsilon_{i,j}}{\sigma}\right)^2 + \left(\frac{V_1(i, j+1) - V_1(i, j) - \varepsilon_{i,j}}{\sigma}\right)^2} \\ &= \frac{\sqrt{2}|c - \varepsilon_{i,j}|}{\sigma}. \end{aligned}$$

This yields

$$\sqrt{\left(\frac{X_1}{\sigma}\right)^2 + \left(\frac{X_2}{\sigma}\right)^2} \sim \chi_2 \left(\frac{\sqrt{2}|c - \varepsilon_{i,j}|}{\sigma} \right).$$

Since $\varepsilon_{i,j}$ is not constant, but a normal distributed random variable with zero mean and standard deviation σ , we have a compound probability distribution:

$$\begin{aligned} &\mathbb{P}_{V_1} \left((\|\Delta^+ F(i, j)\| \leq t) \right) \\ &= \mathbb{P}_{V_1} \left(\sqrt{\left(\frac{X_1}{\sigma}\right)^2 + \left(\frac{X_2}{\sigma}\right)^2} \leq \frac{t}{\sigma} \right) \end{aligned}$$

$$\begin{aligned}
 &= \int_0^{\frac{t}{\sigma}} \int_{-\infty}^{\infty} x \exp\left(-\frac{x^2}{2} - \frac{|c-\eta|^2}{\sigma^2}\right) \underbrace{I_0\left(\frac{\sqrt{2}|c-\eta|}{\sigma}x\right)}_{\text{pdf of } \chi_2\left(\frac{\sqrt{2}|c-\eta|}{\sigma}\right) \text{ for fixed } \eta} \underbrace{\frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{\eta^2}{2\sigma^2}\right)}_{\text{pdf of } \mathcal{N}(0, \sigma^2)} d\eta dx \\
 &= \frac{1}{\sqrt{2\pi\sigma^2}} \int_0^{\frac{t}{\sigma}} x \exp\left(-\frac{x^2}{2}\right) \int_{-\infty}^{\infty} \exp\left(-\frac{(c-\eta)^2}{\sigma^2} - \frac{\eta^2}{2\sigma^2}\right) I_0\left(\frac{\sqrt{2}x}{\sigma}(c-\eta)\right) d\eta dx
 \end{aligned}$$

where we used the symmetry of I_0 . The second equality can be proven analogously. \square

These results are not as strong as the results from Theorem 2.9. By using equation (20) we are able to compute an upper bound for the probability of a type I error. Theorems 2.11 and 2.12 do not provide a similar result for the probability of a type II error.

We can, however, simulate random variables V_1 and V_2 as in Theorem 2.11. This way, we obtain empirical estimates of upper and lower bounds for the probability of a type II error depending on the standard deviation σ of the noise term in the statistical model (12).

Figure 4 shows the result of this simulation for the thresholds $t_{0.05} = 3.2555$ and $t_{0.01} = 4.2792$, that were computed in Section 2.3. A *MATLAB* implementation of the simulation can be found in the appendix.

Theorem 2.12 also gives a second way to numerically obtain upper and lower bounds for the probability of a type II error by numerically integrating the right hand side of equations (29) and (30).

Figure 4: Simulated bounds for the probability of a type II error. We use the thresholds $t_{0.05} = 3.2555$ for $\alpha = 0.05$ and $t_{0.01} = 4.2792$ for $\alpha = 0.01$. (Sample size: 1000000)

3 Binary morphological operations

We now introduce morphological operations. It is our goal to study the influence of these operations on the probabilities of type I and II errors in our testing procedure. Since we can view the output of the testing procedure as a binarization, it is sufficient to only consider *binary* morphological operations. Moreover, we will only study the impact of *binary opening* and *binary closing*. These operations only depend on a limited and fixed number of pixels. In contrast to that, the *convex hull* is a morphological operation depending on all pixels of an image, making it harder to study on a pixel-by-pixel basis.

3.1 Definition of opening & closing

Morphological binary opening and closing are closely related operations. They are both defined as a composition of *binary erosion* and *binary dilation*. Thus we start by defining those operations. It should be noted, that we focus on morphological operations in image processing and thus the definitions might differ from those in other contexts. The definitions of the basic morphology operations are taken from [7].

Definition 3.1. Let $\Theta, \Psi \subseteq \mathbb{Z}^2$.

1. The *binary erosion* of Θ by Ψ is defined as

$$\Theta \ominus \Psi = \left\{ x \in \mathbb{Z}^2 \mid x + b \in \Theta \text{ for every } b \in \Psi \right\}.$$

2. The *binary dilation* of Θ by Ψ is defined as

$$\Theta \oplus \Psi = \left\{ c \in \mathbb{Z}^2 \mid c = a + b \text{ for some } a \in \Theta \text{ and } b \in \Psi \right\}.$$

The set Ψ is called a *structuring element*.

Remark 3.2. The set Ψ can be chosen arbitrarily, although should be chosen to fit the current application.

As we can see, in binary morphology a binary image is a subset of \mathbb{Z}^2 . This subset is the set of points at which the binary image is one. In contrast to that, we aim to study the influence of these morphological operations on the outcome of a statistical test for each individual pixel of an image. This outcome is best represented by a matrix $\mathfrak{J} \in \{0, 1\}^{m \times n}$. Hence, we need to translate the definition of binary opening and closing as operations on subsets of \mathbb{Z}^2 to operations on matrices $\mathfrak{J} \in \{0, 1\}^{m \times n}$. This gives rise to the following definition.

Definition 3.3. Let $m, n \in \mathbb{N}$, $\mathfrak{J} \in \{0, 1\}^{m \times n}$, $\Omega = \{1, \dots, m\} \times \{1, \dots, n\}$ and $\Psi \subseteq \mathbb{Z}^2$ be a structuring element. We call

$$\Theta_{\mathfrak{J}} := \{(i, j) \in \Omega \mid \mathfrak{J}(i, j) = 1\} \subseteq \mathbb{Z}^2$$

the index set of the binary matrix \mathfrak{J} .

1. The *erosion* of the binary matrix \mathfrak{J} by the structuring element Ψ is defined by

$$(\mathfrak{J} \ominus \Psi)(i, j) = \begin{cases} 1, & \text{if } (i, j) \in \Theta_{\mathfrak{J}} \ominus \Psi, \\ 0, & \text{if } (i, j) \notin \Theta_{\mathfrak{J}} \ominus \Psi, \end{cases} \quad (31)$$

for every $(i, j) \in \Omega$.

2. The *dilation* of the binary matrix \mathfrak{J} by the structuring element Ψ is defined by

$$(\mathfrak{J} \oplus \Psi)(i, j) = \begin{cases} 1, & \text{if } (i, j) \in \Theta_{\mathfrak{J}} \oplus \Psi, \\ 0, & \text{if } (i, j) \notin \Theta_{\mathfrak{J}} \oplus \Psi, \end{cases} \quad (32)$$

for every $(i, j) \in \Omega$.

By definition, erosion and dilation of a binary matrix are binary matrices as well, i.e. $\mathfrak{J} \ominus \Psi, \mathfrak{J} \oplus \Psi \in \{0, 1\}^{m \times n}$.

We want to express $\mathfrak{J} \ominus \Psi$ and $\mathfrak{J} \oplus \Psi$ in terms of \mathfrak{J} . This is done in the following lemma.

Lemma 3.4. *Let $m, n \in \mathbb{N}$, $\mathfrak{J} \in \{0, 1\}^{m \times n}$ and $\Psi \subseteq \mathbb{Z}^2$ be a structuring element. Let $(i, j) \in \Omega$. Then we have the following equalities:*

$$(\mathfrak{J} \ominus \Psi)(i, j) = \prod_{(k, l) \in \Psi} \mathfrak{J}(i + k, j + l) \quad (33)$$

$$(\mathfrak{J} \oplus \Psi)(i, j) = 1 - \prod_{(k, l) \in \Psi} (1 - \mathfrak{J}(i - k, j - l)) \quad (34)$$

where we extend the matrix \mathfrak{J} to all of \mathbb{Z}^2 by setting $\mathfrak{J}(k, l) = 0$ for $(k, l) \notin \Omega$.

Proof. Let $\Theta_{\mathfrak{J}}$ be the index set of the binary matrix \mathfrak{J} . We start with the first equality. By definition of binary erosion and using basic properties of set theory, we get the equivalence

$$\begin{aligned} (\mathfrak{J} \ominus \Psi)(i, j) = 1 &\Leftrightarrow (i, j) \in \Theta_{\mathfrak{J}} \ominus \Psi \\ &\Leftrightarrow \forall (k, l) \in \Psi : (i, j) + (k, l) \in \Theta_{\mathfrak{J}} \end{aligned}$$

$$\Leftrightarrow (i, j) \in \bigcap_{(k, l) \in \Psi} (\Theta_{\mathfrak{J}} - (k, l))$$

where we define the sets $\Theta_{\mathfrak{J}} - (k, l) := \{a - (k, l) \mid a \in \Theta_{\mathfrak{J}}\}$ for any $(k, l) \in \mathbb{Z}^2$. The sets $\Theta_{\mathfrak{J}} - (k, l)$ are related to the matrix \mathfrak{J} through the equivalence

$$(i, j) \in (\Theta_{\mathfrak{J}} - (k, l)) \Leftrightarrow \mathfrak{J}(i + k, j + l) = 1.$$

Using this relation, we get the equivalence

$$\begin{aligned} (\mathfrak{J} \ominus \Psi)(i, j) = 1 &\Leftrightarrow (i, j) \in \bigcap_{(k, l) \in \Psi} (\Theta_{\mathfrak{J}} - (k, l)) \\ &\Leftrightarrow \prod_{(k, l) \in \Psi} \mathfrak{J}(i + k, j + l) = 1. \end{aligned}$$

The functions on both sides of this equivalence only take values in $\{0, 1\}$. Thus, we get a full equality

$$(\mathfrak{J} \ominus \Psi)(i, j) = \prod_{(k, l) \in \Psi} \mathfrak{J}(i + k, j + l).$$

This proves the first equality.

The proof of the second equality is similar. First we use the definition of binary dilation and basic set theory properties to get the equivalence

$$\begin{aligned} (\mathfrak{J} \oplus \Psi)(i, j) = 1 &\Leftrightarrow (i, j) \in \Theta_{\mathfrak{J}} \oplus \Psi \\ &\Leftrightarrow \exists (k, l) \in \Psi : (i, j) - (k, l) \in \Theta_{\mathfrak{J}} \\ &\Leftrightarrow (i, j) \in \bigcup_{(k, l) \in \Psi} (\Theta_{\mathfrak{J}} + (k, l)). \end{aligned}$$

The property $(i, j) \in \bigcup_{(k, l) \in \Psi} (\Theta_{\mathfrak{J}} + (k, l))$ is fulfilled, if $\mathfrak{J}(i - k, j - l) = 1$ for any $(k, l) \in \Psi$. This observation yields the equivalence

$$\begin{aligned} (\mathfrak{J} \oplus \Psi)(i, j) = 1 &\Leftrightarrow (i, j) \in \bigcup_{(k, l) \in \Psi} (\Theta_{\mathfrak{J}} + (k, l)) \\ &\Leftrightarrow \prod_{(k, l) \in \Psi} (1 - \mathfrak{J}(i - k, j - l)) = 0. \end{aligned}$$

Since \mathfrak{J} is binary, $\prod_{(k,l) \in \Psi} (1 - \mathfrak{J}(i - k, j - l))$ only takes values in $\{0, 1\}$. Hence, we have the equivalence

$$\begin{aligned} (\mathfrak{J} \oplus \Psi)(i, j) = 1 &\Leftrightarrow \prod_{(k,l) \in \Psi} (1 - \mathfrak{J}(i - k, j - l)) = 0 \\ &\Leftrightarrow 1 - \prod_{(k,l) \in \Psi} (1 - \mathfrak{J}(i - k, j - l)) = 1. \end{aligned}$$

Again, since both sides are binary, this yields a full equality

$$(\mathfrak{J} \oplus \Psi)(i, j) = 1 - \prod_{(k,l) \in \Psi} (1 - \mathfrak{J}(i - k, j - l)).$$

□

Remark 3.5. The extension of \mathfrak{J} to all of \mathbb{Z}^2 is necessary, because in the products of the right hand sides of equations (33) and (34), we might reach indices outside of Ω .

After having defined binary erosion and dilation, we now can define binary opening and closing. Again, we start by defining it for subsets of \mathbb{Z}^2 and then proceed to define it for binary matrices $\mathfrak{J} \in \{0, 1\}^{m \times n}$.

Definition 3.6. Let $\Theta, \Psi \subseteq \mathbb{Z}^2$.

1. The *binary opening* of Θ by a structuring element Ψ is defined as

$$\Theta \circ \Psi = (\Theta \ominus \Psi) \oplus \Psi.$$

2. The *binary closing* of Θ by a structuring element Ψ is defined as

$$\Theta \bullet \Psi = (\Theta \oplus \Psi) \ominus \Psi.$$

As we can see, binary opening and closing are concatenations of binary erosion and dilation. The definitions for matrices are done the same way, as they were done for erosion and dilation of binary matrices.

Definition 3.7. Let $m, n \in \mathbb{N}$, $\mathfrak{J} \in \{0, 1\}^{m \times n}$, $\Psi \subseteq \mathbb{Z}^2$ be a structuring element and $\Theta_{\mathfrak{J}}$ be the index set of \mathfrak{J} .

1. The *opening* of the binary matrix \mathfrak{J} by the structuring element Ψ is defined by

$$(\mathfrak{J} \circ \Psi)(i, j) = \begin{cases} 1, & \text{if } (i, j) \in \Theta_{\mathfrak{J}} \circ \Psi, \\ 0, & \text{if } (i, j) \notin \Theta_{\mathfrak{J}} \circ \Psi, \end{cases} \quad (35)$$

for every $(i, j) \in \Omega$.

2. The *closing* of the binary matrix \mathfrak{J} by the structuring element Ψ is defined by

$$(\mathfrak{J} \bullet \Psi)(i, j) = \begin{cases} 1, & \text{if } (i, j) \in \Theta_{\mathfrak{J}} \bullet \Psi, \\ 0, & \text{if } (i, j) \notin \Theta_{\mathfrak{J}} \bullet \Psi, \end{cases} \quad (36)$$

for every $(i, j) \in \Omega$.

While we defined binary opening and closing for subsets of \mathbb{Z}^2 as concatenations of binary erosion and dilation, we did not define opening and closing of a binary matrix as concatenations of erosion and dilation of binary matrices. The following lemma shows the connection between these operations.

Lemma 3.8. *Let $m, n \in \mathbb{N}$, $\mathfrak{J} \in \{0, 1\}^{m \times n}$ and $\Psi \subseteq \mathbb{Z}^2$ be a structuring element. We have the following connections between opening and closing and erosion and dilation of binary matrices:*

$$(\mathfrak{J} \circ \Psi) = (\mathfrak{J} \ominus \Psi) \oplus \Psi \quad (37)$$

$$(\mathfrak{J} \bullet \Psi) = (\mathfrak{J} \oplus \Psi) \ominus \Psi \quad (38)$$

Proof. To prove these relations, we first show, that $\Theta_{\mathfrak{J} \ominus \Psi} = \Theta_{\mathfrak{J}} \ominus \Psi$ and $\Theta_{\mathfrak{J} \oplus \Psi} = \Theta_{\mathfrak{J}} \oplus \Psi$. By definition of the index set of a binary matrix, we have

$$\begin{aligned} \Theta_{\mathfrak{J} \ominus \Psi} &= \{(i, j) \in \Omega \mid (\mathfrak{J} \ominus \Psi)(i, j) = 1\} \\ &= \{(i, j) \in \Omega \mid (i, j) \in \Theta_{\mathfrak{J}} \ominus \Psi\} \\ &= \Theta_{\mathfrak{J}} \ominus \Psi \end{aligned}$$

. The second equality is proven similarly.

Using this equality, we obtain

$$\begin{aligned}
 (\mathfrak{J} \circ \Psi)(i, j) = 1 &\Leftrightarrow (i, j) \in \Theta_{\mathfrak{J}} \circ \Psi \\
 &\Leftrightarrow (i, j) \in (\Theta_{\mathfrak{J}} \ominus \Psi) \oplus \Psi \\
 &\Leftrightarrow (i, j) \in \Theta_{\mathfrak{J} \ominus \Psi} \oplus \Psi \\
 &\Leftrightarrow ((\mathfrak{J} \ominus \Psi) \oplus \Psi)(i, j) = 1
 \end{aligned}$$

and thus prove the first relation. The proof of the second relation is analogous. \square

After we established this connection, we can use the equalities deduced in Lemma 3.4 for erosion and dilation to derive similar equalities for opening and closing of a binary matrix.

Lemma 3.9. *Let $m, n \in \mathbb{N}$, $\mathfrak{J} \in \{0, 1\}^{m \times n}$ and $\Psi \subseteq \mathbb{Z}^2$ be a structuring element. Let $(i, j) \in \Omega$. Then the following equalities hold:*

$$(\mathfrak{J} \circ \Psi)(i, j) = 1 - \prod_{(k, l) \in \Psi} \left(1 - \left(\prod_{(\tilde{k}, \tilde{l}) \in \Psi} \mathfrak{J}(i - k + \tilde{k}, j - l + \tilde{l}) \right) \right) \quad (39)$$

$$(\mathfrak{J} \bullet \Psi)(i, j) = \prod_{(k, l) \in \Psi} \left(1 - \prod_{(\tilde{k}, \tilde{l}) \in \Psi} (1 - \mathfrak{J}(i + k - \tilde{k}, j + l - \tilde{l})) \right) \quad (40)$$

where we extend the matrix \mathfrak{J} to all of \mathbb{Z}^2 by setting $\mathfrak{J}(k, l) = 0$ for $(k, l) \notin \Omega$.

Proof. We can use the previous lemma, as well as equations (34) and (33) to obtain the first equality

$$\begin{aligned}
 (\mathfrak{J} \circ \Psi)(i, j) &= ((\mathfrak{J} \ominus \Psi) \oplus \Psi)(i, j) \\
 &= 1 - \prod_{(k, l) \in \Psi} (1 - (\mathfrak{J} \ominus \Psi)(i - k, j - l)) \\
 &= 1 - \prod_{(k, l) \in \Psi} \left(1 - \left(\prod_{(\tilde{k}, \tilde{l}) \in \Psi} \mathfrak{J}(i - k + \tilde{k}, j - l + \tilde{l}) \right) \right).
 \end{aligned}$$

Using the same lemma and equations also yields the second equality

$$\begin{aligned}
 (\mathfrak{J} \bullet \Psi)(i, j) &= ((\mathfrak{J} \oplus \Psi) \ominus \Psi)(i, j) \\
 &= \prod_{(k, l) \in \Psi} (\mathfrak{J} \oplus \Psi)(i + k, j + l) \\
 &= \prod_{(k, l) \in \Psi} \left(1 - \prod_{(\tilde{k}, \tilde{l}) \in \Psi} (1 - \mathfrak{J}(i + k - \tilde{k}, j + l - \tilde{l})) \right).
 \end{aligned}$$

This finishes the proof. \square

Remark 3.10. Again, we needed to extend \mathfrak{J} to all of \mathbb{Z}^2 , because we might reach indices outside of Ω in the right hand sides of equations (39) and (40). This will not cause any pixels outside of Ω to be set to one.

Using the previous lemma, we can deduce the following equalities of sets of matrices $\mathfrak{J} \in \{0, 1\}^{m \times n}$.

Lemma 3.11. *Let $m, n \in \mathbb{N}$ and $\Psi \subseteq \mathbb{Z}^2$ be a structuring element. Let $(i, j) \in \Omega$. Then the following equalities hold:*

$$\begin{aligned}
 &\{\mathfrak{J} \in \{0, 1\}^{m \times n} \mid (\mathfrak{J} \circ \Psi)(i, j) = 1\} \\
 &= \bigcup_{(k, l) \in \Psi} \bigcap_{(\tilde{k}, \tilde{l}) \in \Psi} \{\mathfrak{J} \in \{0, 1\}^{m \times n} \mid \mathfrak{J}(i - k + \tilde{k}, j - l + \tilde{l}) = 1\}
 \end{aligned} \tag{41}$$

$$\begin{aligned}
 &\{\mathfrak{J} \in \{0, 1\}^{m \times n} \mid (\mathfrak{J} \bullet \Psi)(i, j) = 1\} \\
 &= \bigcap_{(k, l) \in \Psi} \bigcup_{(\tilde{k}, \tilde{l}) \in \Psi} \{\mathfrak{J} \in \{0, 1\}^{m \times n} \mid \mathfrak{J}(i + k - \tilde{k}, j + l - \tilde{l}) = 1\}
 \end{aligned} \tag{42}$$

Proof. Using equation (39), we obtain the equality

$$\begin{aligned}
 &\{\mathfrak{J} \in \{0, 1\}^{m \times n} \mid (\mathfrak{J} \circ \Psi)(i, j) = 1\} \\
 &= \left\{ \mathfrak{J} \in \{0, 1\}^{m \times n} \mid 1 - \prod_{(k, l) \in \Psi} \left(1 - \left(\prod_{(\tilde{k}, \tilde{l}) \in \Psi} \mathfrak{J}(i - k + \tilde{k}, j - l + \tilde{l}) \right) \right) = 1 \right\} \\
 &= \left\{ \mathfrak{J} \in \{0, 1\}^{m \times n} \mid \prod_{(k, l) \in \Psi} \left(1 - \left(\prod_{(\tilde{k}, \tilde{l}) \in \Psi} \mathfrak{J}(i - k + \tilde{k}, j - l + \tilde{l}) \right) \right) = 0 \right\}.
 \end{aligned}$$

Now, we see, that $\prod_{(k,l) \in \Psi} \left(1 - \left(\prod_{(\tilde{k}, \tilde{l}) \in \Psi} \mathfrak{I}(i - k + \tilde{k}, j - l + \tilde{l})\right)\right) = 0$, if and only if $1 - \left(\prod_{(\tilde{k}, \tilde{l}) \in \Psi} \mathfrak{I}(i - k + \tilde{k}, j - l + \tilde{l})\right) = 0$ for any $(k, l) \in \Psi$. Thus, we get the equality

$$\begin{aligned} & \left\{ \mathfrak{I} \in \{0, 1\}^{m \times n} \mid (\mathfrak{I} \circ \Psi)(i, j) = 1 \right\} \\ &= \left\{ \mathfrak{I} \in \{0, 1\}^{m \times n} \mid \prod_{(k,l) \in \Psi} \left(1 - \left(\prod_{(\tilde{k}, \tilde{l}) \in \Psi} \mathfrak{I}(i - k + \tilde{k}, j - l + \tilde{l})\right)\right) = 0 \right\} \\ &= \bigcup_{(k,l) \in \Psi} \left\{ \mathfrak{I} \in \{0, 1\}^{m \times n} \mid 1 - \left(\prod_{(\tilde{k}, \tilde{l}) \in \Psi} \mathfrak{I}(i - k + \tilde{k}, j - l + \tilde{l})\right) = 0 \right\} \\ &= \bigcup_{(k,l) \in \Psi} \left\{ \mathfrak{I} \in \{0, 1\}^{m \times n} \mid \prod_{(\tilde{k}, \tilde{l}) \in \Psi} \mathfrak{I}(i - k + \tilde{k}, j - l + \tilde{l}) = 1 \right\}. \end{aligned}$$

For fixed $(k, l) \in \Psi$, we have $\prod_{(\tilde{k}, \tilde{l}) \in \Psi} \mathfrak{I}(i - k + \tilde{k}, j - l + \tilde{l}) = 1$, if and only if $\mathfrak{I}(i - k + \tilde{k}, j - l + \tilde{l}) = 1$ for all $(\tilde{k}, \tilde{l}) \in B$. This yields the equality

$$\begin{aligned} & \left\{ \mathfrak{I} \in \{0, 1\}^{m \times n} \mid (\mathfrak{I} \circ \Psi)(i, j) = 1 \right\} \\ &= \bigcup_{(k,l) \in \Psi} \left\{ \mathfrak{I} \in \{0, 1\}^{m \times n} \mid \prod_{(\tilde{k}, \tilde{l}) \in \Psi} \mathfrak{I}(i - k + \tilde{k}, j - l + \tilde{l}) = 1 \right\} \\ &= \bigcup_{(k,l) \in \Psi} \bigcap_{(\tilde{k}, \tilde{l}) \in \Psi} \left\{ \mathfrak{I} \in \{0, 1\}^{m \times n} \mid \mathfrak{I}(i - k + \tilde{k}, j - l + \tilde{l}) = 1 \right\}. \end{aligned}$$

This proves the first equality. The second equality can be proven similarly. \square

3.2 Examples

Before we proceed to prove the main results of this paper, we want to look at examples of binary opening and closing. In the following figures, we display pixels with value one as black. Pixels that were changed by the morphological operations from one to zero will be displayed as transparent and pixels that were changed from zero to one will be displayed as gray.

In figure 5 we see an example of binary morphological opening. We want to examine the effect of morphological opening on the image in 5a. We use a 3×3 pixel structuring element. Applying morphological erosion sets all but one pixel to zero, as can be seen in figure 5b.

(a) Binary image, where the pixels with value one are black.

(b) Result of binary erosion of the image with a 3×3 pixel structuring element. The transparent pixels are now set to zero.

(c) Image after binary opening, i.e. erosion and dilation. The gray pixels were set to one again.

(d) Result of opening. Outliers have been eliminated and edges have been smoothed.

Figure 5: Example of binary morphological opening.

Now, we apply morphological dilation to the eroded image. In figure 5c the changes are highlighted and the result can be seen in figure 5d. The 2×2

pixel square has been eliminated, since it is smaller than the structuring element, that was used. Also, the edges of the larger connected region have been smoothed.

This effect of morphological opening makes it a great tool for the smoothing of edges and outlier elimination.

Figure 6 shows an example of binary morphological closing. We want to perform morphological closing of the image in 6a. Again, we use a 3×3 pixel structuring element. First, morphological dilation is applied. The result of this can be seen in figure 6b. The surrounding pixels of the four pixels, that had a value of one in the original image, have also been set to one by this morphological operation.

(a) Binary image, where the pixels with value one are black.

(b) Image after binary dilation with a 3×3 pixel structuring element. The gray pixels are now set to one.

(c) Image after binary closing, i.e. dilation and erosion. The transparent pixels are set to zero again.

(d) Result of closing. The gaps between pixels have been filled.

Figure 6: Example of binary morphological closing.

In a second step, morphological erosion is applied to the dilated image. Figure 6c highlights the changes of this step and the final result can be seen in figure

6d. The outer pixels are set to zero again, while the gaps between the four pixels, that had a value of one in the original image, have been filled.

For this reason, morphological closing is frequently used as a tool to fill gaps in binary images.

Altogether, both morphological opening and closing are effective tools to smooth edges. Morphological opening achieves this by eliminating outliers, while morphological closing fills gaps.

4 Main results

In Sections 2.3 and 2.4 we examined the probabilities of type I and II errors in the statistical test developed in section 2.2. We are interested in the change of these probabilities when morphological opening and closing are applied to the binarized image obtained as the outcome of the statistical test. One property of morphological opening and closing is $\Theta \circ \Psi \subseteq \Theta \subseteq \Theta \bullet \Psi$ for any structuring element Ψ . From this fact, we can deduce, that morphological opening will lower the probability of a type I error, but increase the probability of a type II error. Morphological closing, on the other hand, will have the opposite effect. While this serves as a qualitative argument for the employment of these operators, we aim at quantifying this change of the probabilities.

We use a square structuring element, since we have the prior information, that the region of interest in the image is rectangular.

The changes of the probability of a type I error after opening and after opening and closing with a square structuring element are quantified in the following theorem.

Theorem 4.1. *Let $m, n \in \mathbb{N}$, $c \in \mathbb{R} \setminus \{0\}$ and $\Omega = \{1, \dots, m\} \times \{1, \dots, n\}$. Assume that F follows the statistical model given in (12) and let $T(i, j)$ be the test statistic as defined in (15) and $H_0(i, j)$ be the null hypothesis as defined in (13).*

Let $\alpha \in (0, 1)$ and t_α a threshold, such that $\mathbb{P}_V(\|\Delta^+ F(i, j)\| \geq t_\alpha) \leq \alpha$ for every $V \in \mathcal{H}_0^+(i, j)$ and $\mathbb{P}_V(\|\Delta^- F(i, j)\| \geq t_\alpha) \leq \alpha$ for every $V \in \mathcal{H}_0^-(i, j)$.

Let \mathfrak{I}_α be the binary image defined by

$$\mathfrak{I}_\alpha(i, j) = \mathbb{1}_{\{T(i, j) \geq t_\alpha\}} \quad (43)$$

for all $(i, j) \in \Omega$.

Let $\varphi \in \mathbb{N}$ be odd. Let $\Phi_\varphi = \left\{-\frac{\varphi-1}{2}, -\frac{\varphi-3}{2}, \dots, \frac{\varphi-3}{2}, \frac{\varphi-1}{2}\right\}$ and $\Psi_\varphi = \Phi_\varphi \times \Phi_\varphi$ be a structuring element. Let $(i, j) \in \Omega$ and $V \in \mathcal{H}_0(i, j)$. Then the following inequalities hold:

$$\mathbb{P}_V((\mathfrak{I}_\alpha \circ \Psi_\varphi)(i, j) = 1) \leq \varphi \alpha^{\frac{\varphi+1}{2}} \quad (44)$$

$$\mathbb{P}_V(((\mathfrak{I}_\alpha \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 1) \leq \varphi^3 \alpha^{\frac{\varphi+1}{2}} \quad (45)$$

Proof. We start with the proof of inequality (44). We aim to find an upper bound for the probability

$$\mathbb{P}_V((\mathfrak{I}_\alpha \circ \Psi_\varphi)(i, j) = 1)$$

for $V \in \mathcal{H}_0(i, j)$.

We will perform some preparatory work first. As discussed in Section 2.1, any matrix $V \in \mathcal{V}_c^{m,n}$ is uniquely defined by the top left corner (κ_1, λ_1) and bottom right corner (κ_2, λ_2) of the rROI $\Lambda = \{\kappa_1, \dots, \kappa_2\} \times \{\lambda_1, \dots, \lambda_2\}$ contained in V .

We have assumed, that $V \in \mathcal{H}_0(i, j)$. As we have seen in Section 2.2 the null hypothesis is equivalent to $(i, j) \notin \Lambda$. If $(i, j) \notin \Lambda$, this implies, that $i < \kappa_1$ or $j < \lambda_1$ or $i > \kappa_2$ or $j > \lambda_2$. These four cases are not mutually exclusive. We have also seen before, that the first two cases imply $\|\Delta^- V(i, j)\| = 0$ and the latter two imply $\|\Delta^+ V(i, j)\| = 0$.

Based on this knowledge, we can split up the sets $\mathcal{H}_0^+(i, j)$ and $\mathcal{H}_0^-(i, j)$ as defined in (17) and (18). We define the sets

$$\begin{aligned} \mathcal{H}_0^{(1)}(i, j) &:= \left\{ V \in \mathcal{V}_c^{m,n} \mid V(\tilde{i}, \tilde{j}) = 0 \text{ for all } (\tilde{i}, \tilde{j}) \in \{1, \dots, i\} \times \{1, \dots, n\} \right\}, \\ \mathcal{H}_0^{(2)}(i, j) &:= \left\{ V \in \mathcal{V}_c^{m,n} \mid V(\tilde{i}, \tilde{j}) = 0 \text{ for all } (\tilde{i}, \tilde{j}) \in \{1, \dots, m\} \times \{1, \dots, j\} \right\}, \\ \mathcal{H}_0^{(3)}(i, j) &:= \left\{ V \in \mathcal{V}_c^{m,n} \mid V(\tilde{i}, \tilde{j}) = 0 \text{ for all } (\tilde{i}, \tilde{j}) \in \{i, \dots, m\} \times \{1, \dots, n\} \right\}, \\ \mathcal{H}_0^{(4)}(i, j) &:= \left\{ V \in \mathcal{V}_c^{m,n} \mid V(\tilde{i}, \tilde{j}) = 0 \text{ for all } (\tilde{i}, \tilde{j}) \in \{1, \dots, m\} \times \{j, \dots, n\} \right\} \end{aligned}$$

and get $\mathcal{H}_0^-(i, j) = \mathcal{H}_0^{(1)}(i, j) \cup \mathcal{H}_0^{(2)}(i, j)$ and $\mathcal{H}_0^+(i, j) = \mathcal{H}_0^{(3)}(i, j) \cup \mathcal{H}_0^{(4)}(i, j)$. Furthermore, this implies $\mathcal{H}_0(i, j) = \bigcup_{u=1}^4 \mathcal{H}_0^{(u)}(i, j)$.

Depending on which of these sets V belongs to, the rROI is located below/right of/above/left relative to the pixel (i, j) . This means, that all of the pixels above/left of/below/right of the index (i, j) are not part of the rROI.

Assume the first case, i.e. $V \in \mathcal{H}_0^{(1)}(i, j)$. This implies that

$$\|\Delta^- V(i, 1)\| = \dots = \|\Delta^- V(i, n)\| = 0.$$

In a first step, we use equation (41) and the fact, that $\Psi_\varphi = \Phi_\varphi \times \Phi_\varphi$ to write the left hand side of inequality (44) as

$$\begin{aligned} & \mathbb{P}_V((\mathfrak{I}_\alpha \circ \Psi_\varphi)(i, j) = 1) \\ &= \mathbb{P}_V\left(\bigcup_{(k, l) \in \Psi_\varphi} \bigcap_{(\tilde{k}, \tilde{l}) \in \Psi_\varphi} \{\mathfrak{I}_\alpha(i - k + \tilde{k}, j - l + \tilde{l}) = 1\}\right) \\ &= \mathbb{P}_V\left(\bigcup_{k, l \in \Phi_\varphi} \bigcap_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \{\mathfrak{I}_\alpha(i - k + \tilde{k}, j - l + \tilde{l}) = 1\}\right). \end{aligned}$$

Using sub-additivity we can bound this from above by writing it as a sum over $l \in \Phi_\varphi$ and get

$$\begin{aligned} & \mathbb{P}_V((\mathfrak{I}_\alpha \circ \Psi_\varphi)(i, j) = 1) \\ & \leq \sum_{l \in \Phi_\varphi} \mathbb{P}_V\left(\bigcup_{k \in \Phi_\varphi} \bigcap_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \{\mathfrak{I}_\alpha(i - k + \tilde{k}, j - l + \tilde{l}) = 1\}\right). \end{aligned}$$

By dropping every term except for $\tilde{k} = k$ in the intersection inside, we obtain

$$\begin{aligned} & \mathbb{P}_V((\mathfrak{I}_\alpha \circ \Psi_\varphi)(i, j) = 1) \\ & \leq \sum_{l \in \Phi_\varphi} \mathbb{P}_V\left(\bigcup_{k \in \Phi_\varphi} \bigcap_{\tilde{k}=k, \tilde{l} \in \Phi_\varphi} \{\mathfrak{I}_\alpha(i - k + \tilde{k}, j - l + \tilde{l}) = 1\}\right) \\ & = \sum_{l \in \Phi_\varphi} \mathbb{P}_V\left(\bigcup_{k \in \Phi_\varphi} \bigcap_{\tilde{l} \in \Phi_\varphi} \{\mathfrak{I}_\alpha(i, j - l + \tilde{l}) = 1\}\right). \end{aligned}$$

The events inside the probability do not depend on $k \in \Phi_\varphi$ anymore, which

yields

$$\bigcup_{k \in \Phi_\varphi} \bigcap_{\tilde{l} \in \Phi_\varphi} \{\mathfrak{I}_\alpha(i, j - l + \tilde{l}) = 1\} = \bigcap_{\tilde{l} \in \Phi_\varphi} \{\mathfrak{I}_\alpha(i, j - l + \tilde{l}) = 1\}.$$

By plugging this in, we obtain

$$\mathbb{P}_V((\mathfrak{I}_\alpha \circ \Psi_\varphi)(i, j) = 1) \leq \sum_{l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{\tilde{l} \in \Phi_\varphi} \{\mathfrak{I}_\alpha(i, j - l + \tilde{l}) = 1\} \right).$$

We have defined the binary \mathfrak{I}_α by setting $\mathfrak{I}_\alpha(i, j) = \mathbf{1}_{\{T(i, j) \geq t_\alpha\}}$. Using this definition and the definition of $T(i, j)$ we can rewrite the upper bound as

$$\begin{aligned} & \sum_{l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{\tilde{l} \in \Phi_\varphi} \{\mathfrak{I}_\alpha(i, j - l + \tilde{l}) = 1\} \right) \\ &= \sum_{l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{\tilde{l} \in \Phi_\varphi} \{T(i, j - l + \tilde{l}) \geq t_\alpha\} \right) \\ &= \sum_{l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{\tilde{l} \in \Phi_\varphi} \left(\{\|\Delta^+ F(i, j - l + \tilde{l})\| \geq t_\alpha\} \cap \{\|\Delta^- F(i, j - l + \tilde{l})\| \geq t_\alpha\} \right) \right). \end{aligned}$$

By dropping the events $\{\|\Delta^+ F(i, j - l + \tilde{l})\| \geq t_\alpha\}$, we get

$$\begin{aligned} & \mathbb{P}_V((\mathfrak{I}_\alpha \circ \Psi_\varphi)(i, j) = 1) \\ & \leq \sum_{l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{\tilde{l} \in \Phi_\varphi} \left(\{\|\Delta^+ F(i, j - l + \tilde{l})\| \geq t_\alpha\} \cap \{\|\Delta^- F(i, j - l + \tilde{l})\| \geq t_\alpha\} \right) \right) \\ & \leq \sum_{l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{\tilde{l} \in \Phi_\varphi} \{\|\Delta^- F(i, j - l + \tilde{l})\| \geq t_\alpha\} \right). \end{aligned}$$

We now define a second set $\tilde{\Phi}_\varphi = \left\{ -\frac{\varphi-1}{2}, -\frac{\varphi-5}{2}, \dots, \frac{\varphi-5}{2}, \frac{\varphi-1}{2} \right\}$. We have $\tilde{\Phi}_\varphi \subseteq \Phi_\varphi$. Since $\Delta^- F(i, j)$ only depends on the pixels (i, j) , $(i-1, j)$ and $(i, j-1)$, the set $\{\|\Delta^- F(i, j - l + \tilde{l})\| \mid \tilde{l} \in \tilde{\Phi}_\varphi\}$ is a set of independent random variables for fixed $l \in \Phi_\varphi$, see figure 7.

Figure 7: The random variable $\|\Delta^- F(i, j)\|$ only depends on the green pixels, $\|\Delta^- F(i, j - 2)\|$ depends on the red pixels and $\|\Delta^- F(i, j + 2)\|$ on the blue pixels. Since these are all distinct from another, the random variables are independent.

We drop the terms in $\Phi_\varphi \setminus \tilde{\Phi}_\varphi$ and use the independence to obtain

$$\begin{aligned}
 \mathbb{P}_V((\mathfrak{I}_\alpha \circ \Psi_\varphi)(i, j) = 1) &\leq \sum_{l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{\tilde{l} \in \Phi_\varphi} \left\{ \|\Delta^- F(i, j - l + \tilde{l})\| \geq t_\alpha \right\} \right) \\
 &\leq \sum_{l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{\tilde{l} \in \tilde{\Phi}_\varphi} \left\{ \|\Delta^- F(i, j - l + \tilde{l})\| \geq t_\alpha \right\} \right) \\
 &= \sum_{l \in \Phi_\varphi} \prod_{\tilde{l} \in \tilde{\Phi}_\varphi} \mathbb{P}_V \left(\|\Delta^- F(i, j - l + \tilde{l})\| \geq t_\alpha \right).
 \end{aligned}$$

At the start of this proof, we have decomposed the set $\mathcal{H}_0(i, j)$ into four subsets. This was done by exploiting the prior knowledge, that V contains a rectangular region of interest. We assumed the case $V \in \mathcal{H}_0^{(1)}(i, j) \subseteq \mathcal{H}_0^-(i, j)$, which means

$$\|\Delta^- V(i, 1)\| = \dots = \|\Delta^- V(i, n)\| = 0.$$

This implies, that for fixed $l \in \Phi_\varphi$ the null hypotheses $H_0(i, j - l + \tilde{l})$ are true for all $\tilde{l} \in \tilde{\Phi}_\varphi$ and hence $V \in \bigcap_{\tilde{l} \in \tilde{\Phi}_\varphi} \mathcal{H}_0(i, j - l + \tilde{l})$. Furthermore, we have assumed, that the threshold t_α was chosen, such that for $V \in \mathcal{H}_0^-(i, j)$ we have $\mathbb{P}_V(\|\Delta^- F(i, j)\| \geq t_\alpha) \leq \alpha$. Such a threshold can be obtained by using Lemma 2.8 and Theorem 2.9. This knowledge yields the upper bound

$$\begin{aligned} \mathbb{P}_V((\mathfrak{I}_\alpha \circ \Psi_\varphi)(i, j) = 1) &\leq \sum_{l \in \Phi_\varphi} \prod_{\tilde{l} \in \tilde{\Phi}_\varphi} \mathbb{P}_V(\|\Delta^- F(i, j - l + \tilde{l})\| \geq t_\alpha) \\ &\leq \sum_{l \in \Phi_\varphi} \prod_{\tilde{l} \in \tilde{\Phi}_\varphi} \alpha \\ &= |\Phi_\varphi| \alpha^{|\tilde{\Phi}_\varphi|} \\ &= \varphi \alpha^{\frac{\varphi+1}{2}}. \end{aligned}$$

This proves the first inequality for the first case. The other three cases can be proven analogously by swapping the roles of k or \tilde{k} with l or \tilde{l} , respectively and/or by replacing Δ^- by Δ^+ . This finishes the proof of the first inequality.

For the proof of the second inequality, we want to exploit our prior knowledge on V again. As already stated in the proof of the first inequality, we see, that $H_0(i, j)$ is equivalent to $(i, j) \notin \Lambda$, which is equivalent to at least one of the cases $V \in \mathcal{H}_0^{(u)}(i, j)$ for $u \in \{1, 2, 3, 4\}$.

Again we assume the first case, i.e. $V \in \mathcal{H}_0^{(1)}(i, j)$. This implies, that the null hypotheses $H_0(\tilde{i}, 1), \dots, H_0(\tilde{i}, n)$ are true for all $\tilde{i} \in \{1, \dots, i\}$. It also implies

$$\|\Delta^- V(\tilde{i}, 1)\| = \dots = \|\Delta^- V(\tilde{i}, n)\| = 0$$

for all $\tilde{i} \in \{1, \dots, i\}$.

Set $k_0 = -\frac{\varphi-1}{2}$ and $l_0 = 0$. Then $(k_0, l_0) \in \Psi_\varphi$ and we get that the null hypotheses $H_0(i + k_0 - \tilde{k}, j + l_0 - \tilde{l})$ are true for all $\tilde{k}, \tilde{l} \in \Phi_\varphi$. Hence, we have $V \in \cap_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \mathcal{H}_0(i + k_0 - \tilde{k}, j + l_0 - \tilde{l})$ as well as $\|\Delta^- V(i + k_0 - \tilde{k}, j + l_0 - \tilde{l})\| = 0$ for all $\tilde{k}, \tilde{l} \in \Phi_\varphi$.

Define $\mathfrak{K}_\alpha = \mathfrak{I}_\alpha \circ \Psi_\varphi$. We use equation (42) and $\Psi_\varphi = \Phi_\varphi \times \Phi_\varphi$ to write the left hand side of inequality (45) as

$$\begin{aligned} \mathbb{P}_V((\mathfrak{K}_\alpha \bullet \Psi_\varphi)(i, j) = 1) &= \mathbb{P}_V\left(\bigcap_{(k, l) \in \Psi_\varphi} \bigcup_{(\tilde{k}, \tilde{l}) \in \Psi_\varphi} \{\mathfrak{K}_\alpha(i + k - \tilde{k}, j + l - \tilde{l}) = 1\}\right) \\ &= \mathbb{P}_V\left(\bigcap_{k, l \in \Phi_\varphi} \bigcup_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \{\mathfrak{K}_\alpha(i + k - \tilde{k}, j + l - \tilde{l}) = 1\}\right). \end{aligned}$$

By dropping every term in the intersection except for $k = k_0$ and $l = l_0$ we can bound this from above by

$$\begin{aligned} \mathbb{P}_V((\mathfrak{K}_\alpha \bullet \Psi_\varphi)(i, j) = 1) &= \mathbb{P}_V\left(\bigcap_{k, l \in \Phi_\varphi} \bigcup_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \{\mathfrak{K}_\alpha(i + k - \tilde{k}, j + l - \tilde{l}) = 1\}\right) \\ &\leq \mathbb{P}_V\left(\bigcup_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \{\mathfrak{K}_\alpha(i + k_0 - \tilde{k}, j + l_0 - \tilde{l}) = 1\}\right) \\ &= \mathbb{P}_V\left(\bigcup_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \{\mathfrak{K}_\alpha(i + k_0 - \tilde{k}, j - \tilde{l}) = 1\}\right). \end{aligned}$$

Using sub-additivity to write this as the sum over all $\tilde{k}, \tilde{l} \in \Phi_\varphi$ yields

$$\mathbb{P}_V((\mathfrak{K}_\alpha \bullet \Psi_\varphi)(i, j) = 1) \leq \sum_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \mathbb{P}_V(\mathfrak{K}_\alpha(i + k_0 - \tilde{k}, j - \tilde{l}) = 1).$$

Plugging in the definition of \mathfrak{K}_α we obtain

$$\mathbb{P}_V((\mathfrak{K}_\alpha \bullet \Psi_\varphi)(i, j) = 1) \leq \sum_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \mathbb{P}_V((\mathfrak{I}_\alpha \circ \Psi_\varphi)(i + k_0 - \tilde{k}, j - \tilde{l}) = 1).$$

As we have seen, the null hypotheses $H_0(i + k_0 - \tilde{k}, j + l_0 - \tilde{l})$ are true for all $\tilde{k}, \tilde{l} \in \Phi_\varphi$, which implies $V \in \bigcap_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \mathcal{H}_0(i + k_0 - \tilde{k}, j - \tilde{l})$. Thus, we can use inequality (44) to get the upper bound

$$\begin{aligned} \mathbb{P}_V((\mathfrak{K}_\alpha \bullet \Psi_\varphi)(i, j) = 1) &\leq \sum_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \mathbb{P}_V((\mathfrak{I}_\alpha \circ \Psi_\varphi)(i + k_0 - \tilde{k}, j - \tilde{l}) = 1) \\ &\leq \sum_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \varphi \alpha^{\frac{\varphi+1}{2}} \\ &= \varphi^3 \alpha^{\frac{\varphi+1}{2}}. \end{aligned}$$

This proves the inequality in the first case. The other cases are proven analogously by taking $k_0 = 0, l_0 = -\frac{\varphi-1}{2}$ in the second case, $k_0 = \frac{\varphi-1}{2}, l_0 = 0$ in the third case and $k_0 = 0, l_0 = \frac{\varphi-1}{2}$ in the fourth case. In the second and fourth case, the roles of Δ^+ and Δ^- are swapped. This finishes the proof of the second inequality and thus the proof of the theorem. \square

Similar to the previous theorem, we want to quantify the change of the probabilities of a type II error, when morphological opening and closing are applied. We will need the additional assumption, that the region of interest is sufficiently large, i.e. larger than the structuring element. Otherwise, even if there are no errors in the binarization through the statistical test, morphological opening will classify all pixels as background and thus the probability of a type II error cannot be bound anymore.

Theorem 4.2. *Let $m, n \in \mathbb{N}$, $c \in \mathbb{R} \setminus \{0\}$ and $\Omega = \{1, \dots, m\} \times \{1, \dots, n\}$. Assume that F follows the statistical model given in (12) and let $T(i, j)$ be the test statistic as defined in (15) and $H_1(i, j)$ be the alternative hypothesis as defined in (14). Let t be a threshold, such that*

$$\mathbb{P}_V(T(i, j) \leq t) \leq \beta$$

for all $V \in \mathcal{H}_1(i, j)$. Let \mathfrak{I} be the binary image defined by

$$\mathfrak{I}(i, j) = \mathbb{1}_{\{T(i, j) \geq t\}} \quad (46)$$

for all $(i, j) \in \Omega$.

Let $\varphi \in \mathbb{N}$ be odd. Let $\Phi_\varphi = \{-\frac{\varphi-1}{2}, -\frac{\varphi-3}{2}, \dots, \frac{\varphi-3}{2}, \frac{\varphi-1}{2}\}$ and $\Psi_\varphi = \Phi_\varphi \times \Phi_\varphi$ be a structuring element. Let $(i, j) \in \Omega$ and $V \in \mathcal{H}_1(i, j)$.

Denote by $\Lambda = \{\kappa_1, \dots, \kappa_2\} \times \{\lambda_1, \dots, \lambda_2\}$ the rROI contained in V . Let $\min\{\kappa_2 - \kappa_1 + 1, \lambda_2 - \lambda_1 + 1\} \geq \varphi$. Then the following inequalities hold:

$$\mathbb{P}_V((\mathcal{I} \circ \Psi_\varphi)(i, j) = 0) \leq \varphi^2 \beta \quad (47)$$

$$\mathbb{P}_V(((\mathcal{I} \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 0) \leq \varphi^2 \beta \quad (48)$$

Proof. We start by proving inequality (47). We use a similar approach as in the proof of inequality (45) by finding indices $(k_0, l_0) \in \Psi_\varphi$, such that the alternative hypotheses $H_1(i - k_0 + \tilde{k}, j - l_0 + \tilde{l})$ are true for all $\tilde{k}, \tilde{l} \in \Phi_\varphi$. Define

$$\begin{aligned} k_0 &= \min \left\{ i - \kappa_1 - \frac{\varphi-1}{2}, 0 \right\} - \min \left\{ \kappa_2 - i - \frac{\varphi-1}{2}, 0 \right\}, \\ l_0 &= \min \left\{ j - \lambda_1 - \frac{\varphi-1}{2}, 0 \right\} - \min \left\{ \lambda_2 - j - \frac{\varphi-1}{2}, 0 \right\}. \end{aligned}$$

First we show, that k_0 can only take the values $i - \kappa_1 - \frac{\varphi-1}{2}$, $-\kappa_2 + i + \frac{\varphi-1}{2}$ or 0. Then we distinguish the three possible cases to show, that $\kappa_1 \leq i - k_0 + \tilde{k} \leq \kappa_2$ in every case. Similarly, we obtain $\lambda_1 \leq j - l_0 + \tilde{l} \leq \lambda_2$ and hence the alternative hypotheses $H_1(i - k_0 + \tilde{k}, j - l_0 + \tilde{l})$ are true for all $\tilde{k}, \tilde{l} \in \Phi_\varphi$.

If $i - \kappa_1 - \frac{\varphi-1}{2} \leq 0$, by using the assumption $\kappa_2 - \kappa_1 + 1 \geq \varphi$ we obtain

$$\begin{aligned} \kappa_2 - i - \frac{\varphi-1}{2} &= \kappa_2 - i - \frac{\varphi-1}{2} + \left(i - \kappa_1 - \frac{\varphi-1}{2} \right) - \left(i - \kappa_1 - \frac{\varphi-1}{2} \right) \\ &= \kappa_2 - \kappa_1 + 1 - \varphi - i + \kappa_1 + \frac{\varphi-1}{2} \\ &\geq -i + \kappa_1 + \frac{\varphi-1}{2} \\ &\geq 0 \end{aligned}$$

and thus $k_0 = i - \kappa_1 - \frac{\varphi-1}{2}$. On the other hand, if $\kappa_2 - i - \frac{\varphi-1}{2} \leq 0$, we obtain

$$i - \kappa_1 - \frac{\varphi-1}{2} = i - \kappa_1 - \frac{\varphi-1}{2} + \left(\kappa_2 - i - \frac{\varphi-1}{2} \right) - \left(\kappa_2 - i - \frac{\varphi-1}{2} \right)$$

$$\begin{aligned}
 &= \kappa_2 - \kappa_1 + 1 - \varphi - \kappa_2 + i + \frac{\varphi - 1}{2} \\
 &\geq -\kappa_2 + i + \frac{\varphi - 1}{2} \\
 &\geq 0
 \end{aligned}$$

and hence $k_0 = -\kappa_2 + i + \frac{\varphi-1}{2}$, which shows, that k_0 can only take the values $i - \kappa_1 - \frac{\varphi-1}{2}$, $-\kappa_2 + i + \frac{\varphi-1}{2}$ or 0.

Assume $k_0 = 0$. This implies $i - \kappa_1 - \frac{\varphi-1}{2} \geq 0$ as well as $\kappa_2 - i - \frac{\varphi-1}{2} \geq 0$ and thus for $\tilde{k} \in \Phi_\varphi$ we get

$$\kappa_1 \leq i - \frac{\varphi - 1}{2} \leq i + \tilde{k} = i - k_0 + \tilde{k} = i + \tilde{k} \leq i + \frac{\varphi - 1}{2} \leq \kappa_2.$$

Now assume $k_0 = i - \kappa_1 - \frac{\varphi-1}{2}$. Then $i - k_0 + \tilde{k} = \kappa_1 + \frac{\varphi-1}{2} + \tilde{k}$. Using $\kappa_2 - \kappa_1 + 1 \geq \varphi$ yields for every $\tilde{k} \in \Phi_\varphi$

$$\begin{aligned}
 \kappa_1 &= \kappa_1 + \frac{\varphi - 1}{2} - \frac{\varphi - 1}{2} \\
 &\leq \kappa_1 + \frac{\varphi - 1}{2} + \tilde{k} \\
 &\leq \kappa_1 + \frac{\varphi - 1}{2} + \frac{\varphi - 1}{2} \\
 &= \kappa_1 + \varphi - 1 \\
 &\leq \kappa_2
 \end{aligned}$$

which proves the second case.

Lastly, assume $k_0 = -\kappa_2 + i + \frac{\varphi-1}{2}$. Then $i - k_0 + \tilde{k} = \kappa_2 - \frac{\varphi-1}{2} + \tilde{k}$. Again, by $\kappa_2 - \kappa_1 + 1 \geq \varphi$ we obtain for every $\tilde{k} \in \Phi_\varphi$

$$\begin{aligned}
 \kappa_1 &\leq \kappa_2 - \varphi + 1 \\
 &= \kappa_2 - \frac{\varphi - 1}{2} - \frac{\varphi - 1}{2} \\
 &\leq \kappa_2 - \frac{\varphi - 1}{2} + \tilde{k} \\
 &\leq \kappa_2 - \frac{\varphi - 1}{2} + \frac{\varphi - 1}{2} \\
 &= \kappa_2.
 \end{aligned}$$

Thus, the alternative hypotheses $H_1(i - k_0 + \tilde{k}, j - l_0 + \tilde{l})$ are true for all $\tilde{k}, \tilde{l} \in \Phi_\varphi$, which implies $V \in \bigcap_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \mathcal{H}_1(i - k_0 + \tilde{k}, j - l_0 + \tilde{l})$.

Using this, we can prove inequality (47). We start by using equation (41) and $\Psi_\varphi = \Phi_\varphi \times \Phi_\varphi$ to write the left hand side of inequality (47) as

$$\begin{aligned} \mathbb{P}_V((\mathfrak{I} \circ \Psi_\varphi)(i, j) = 0) &= \mathbb{P}_V \left(\bigcap_{(k, l) \in \Psi_\varphi} \bigcup_{(\tilde{k}, \tilde{l}) \in \Psi_\varphi} \{\mathfrak{I}(i - k + \tilde{k}, j - l + \tilde{l}) = 0\} \right) \\ &= \mathbb{P}_V \left(\bigcap_{k, l \in \Phi_\varphi} \bigcup_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \{\mathfrak{I}(i - k + \tilde{k}, j - l + \tilde{l}) = 0\} \right). \end{aligned}$$

We drop every term in the intersection except $k = k_0, l = l_0$ to bound this by

$$\begin{aligned} \mathbb{P}_V((\mathfrak{I} \circ \Psi_\varphi)(i, j) = 0) &= \mathbb{P}_V \left(\bigcap_{k, l \in \Phi_\varphi} \bigcup_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \{\mathfrak{I}(i - k + \tilde{k}, j - l + \tilde{l}) = 0\} \right) \\ &\leq \mathbb{P}_V \left(\bigcup_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \{\mathfrak{I}(i - k_0 + \tilde{k}, j - l_0 + \tilde{l}) = 0\} \right). \end{aligned}$$

We use sub-additivity to write this as the sum over all $\tilde{k}, \tilde{l} \in \Phi_\varphi$ and obtain

$$\mathbb{P}_V((\mathfrak{I} \circ \Psi_\varphi)(i, j) = 0) \leq \sum_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \mathbb{P}_V(\mathfrak{I}(i - k_0 + \tilde{k}, j - l_0 + \tilde{l}) = 0).$$

Using the fact, that $V \in \bigcap_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \mathcal{H}_1(i - k_0 + \tilde{k}, j - l_0 + \tilde{l})$ as well as the definition of \mathfrak{I} and the choice of the threshold t we get the upper bound

$$\begin{aligned} \mathbb{P}_V((\mathfrak{I} \circ \Psi_\varphi)(i, j) = 0) &\leq \sum_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \mathbb{P}_V(\mathfrak{I}(i - k_0 + \tilde{k}, j - l_0 + \tilde{l}) = 0) \\ &= \sum_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \mathbb{P}_V(T(i - k_0 + \tilde{k}, j - l_0 + \tilde{l}) \leq t) \\ &\leq \sum_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \beta \\ &= |\Phi_\varphi|^2 \beta \end{aligned}$$

$$= \varphi^2 \beta.$$

This finishes the proof of the first inequality.

To prove the second inequality, we define $\mathfrak{K} = \mathfrak{J} \circ \Psi_\varphi$. We aim to find an upper bound for the probability

$$\mathbb{P}_V((\mathfrak{K} \bullet \Psi_\varphi)(i, j) = 0)$$

for $V \in \mathcal{H}_1(i, j)$. We use equation (42) and $\Psi_\varphi = \Phi_\varphi \times \Phi_\varphi$ and get

$$\begin{aligned} \mathbb{P}_V((\mathfrak{K} \bullet \Psi_\varphi)(i, j) = 0) &= \mathbb{P}_V \left(\bigcup_{(k, l) \in \Psi_\varphi} \bigcap_{(\tilde{k}, \tilde{l}) \in \Psi_\varphi} \{ \mathfrak{K}(i + k - \tilde{k}, j + l - \tilde{l}) = 0 \} \right) \\ &= \mathbb{P}_V \left(\bigcup_{k, l \in \Phi_\varphi} \bigcap_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \{ \mathfrak{K}(i + k - \tilde{k}, j + l - \tilde{l}) = 0 \} \right). \end{aligned}$$

We drop every term in the intersection except for $\tilde{k} = k, \tilde{l} = l$. This increases the probability and we obtain

$$\begin{aligned} \mathbb{P}_V((\mathfrak{K} \bullet \Psi_\varphi)(i, j) = 0) &= \mathbb{P}_V \left(\bigcup_{(k, l) \in \Psi_\varphi} \bigcap_{(\tilde{k}, \tilde{l}) \in \Psi_\varphi} \{ \mathfrak{K}(i + k - \tilde{k}, j + l - \tilde{l}) = 0 \} \right) \\ &\leq \mathbb{P}_V \left(\bigcup_{k, l \in \Phi_\varphi} \bigcap_{\tilde{k}=k, \tilde{l}=l} \{ \mathfrak{K}(i + k - \tilde{k}, j + l - \tilde{l}) = 0 \} \right) \\ &= \mathbb{P}_V \left(\bigcup_{k, l \in \Phi_\varphi} \{ \mathfrak{K}(i, j) = 0 \} \right) \\ &= \mathbb{P}_V(\mathfrak{K}(i, j) = 0). \end{aligned}$$

Plugging in the definition of \mathfrak{K} this inequality becomes

$$\mathbb{P}_V((\mathfrak{K} \bullet \Psi_\varphi)(i, j) = 0) \leq \mathbb{P}_V((\mathfrak{J} \circ \Psi_\varphi)(i, j) = 0).$$

Since $V \in \mathcal{H}_1(i, j)$, we can apply inequality (47) and obtain the upper bound

$$\begin{aligned} \mathbb{P}_V((\mathfrak{K} \bullet \Psi_\varphi)(i, j) = 0) &\leq \mathbb{P}_V((\mathfrak{J} \circ \Psi_\varphi)(i, j) = 0) \\ &\leq \varphi^2 \beta. \end{aligned}$$

This proves the second inequality and thus finishes the proof. \square

Remark 4.3. The bounds in the previous theorem hold for all pixels within the region of interest, i.e. also for the edges and corners of the region of interest.

For pixels with a sufficient distance from the edges of the region of interest, we can also prove the upper bound

$$\mathbb{P}_V(((\mathfrak{J} \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 0) \leq \varphi^{10} \beta^4.$$

A proof can be found in the appendix. This only improves the bound for very small values of β .

We employ morphological closing to reduce the number of type II errors. This is not represented in the upper bound in inequality (48). This is due to the fact, that the pixels are not independent anymore after morphological opening has been applied. Furthermore, applying morphological closing after morphological opening does not necessarily result in a lower amount of type II errors compared to the amount of such errors through binarization. Especially for bigger values of σ , this effect becomes clear. This behaviour can be observed in the simulation results.

5 Simulation results

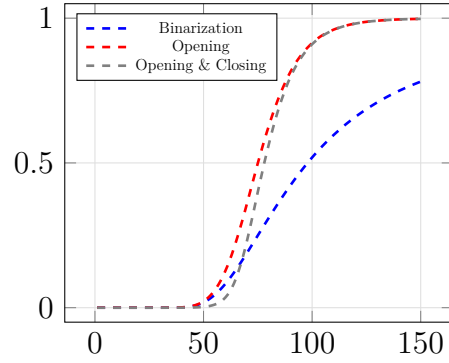

(a) Proportion of type I errors for images with size 128×128 .

(b) Proportion of type II errors for images with size 128×128 .

(c) Proportion of type I errors for images with size 256×256 .

(d) Proportion of type II errors for images with size 256×256 .

(e) Proportion of type I errors for images with size 512×512 .

(f) Proportion of type II errors for images with size 512×512 .

Figure 8: Proportion of type I & II errors after binarization, opening and closing. The x -axes display the standard deviation σ and the y -axes the proportion of falsely classified pixels. For sizes 128×128 , 256×256 , 512×512 the images were randomly generated with 5 images per size. For each image 50 different noises were randomly generated. We used a 3×3 pixel structuring element and chose $\alpha = 0.05$.

In figure 9 we see the proportion of falsely classified pixels after binarization through the statistical test, opening and closing. We randomly generated 15 images with a rectangular region of interest with a checkerboard pattern. We created 5 images each for sizes 128×128 , 256×256 and 512×512 pixels. After binarization, the proportion of background pixels that were falsely classified as foreground is low and below the chosen statistical significance of $\alpha = 0.05$. It is almost constant across all values of the standard deviation σ . We performed opening and closing with a 3×3 pixel structuring element. Opening reduces the proportion of falsely classified background pixels to almost zero. Applying closing does not change that.

In contrast to that, the proportion of falsely classified foreground pixels is almost zero for low standard deviations σ but greatly increases, as σ increases. For high values of σ opening greatly increases the proportion of falsely classified foreground pixels. Closing fixes this only to a certain extent. For values up to $\sigma = 68$ it reduces the proportion of type II errors below that of binarization. For higher values of σ this improvement can not be observed and the effect of closing becomes negligible.

Using a relaxed statistical significance $\tilde{\alpha} = \left(\frac{\alpha}{\varphi^3}\right)^{\frac{2}{\varphi+1}}$ to calculate the thresholding parameter $t_{\tilde{\alpha}}$, yields

$$\mathbb{P}_V(((\mathcal{J}_{\tilde{\alpha}} \circ \Psi_{\varphi}) \bullet \Psi_{\varphi})(i, j) = 1) \leq \varphi^3 \left(\left(\frac{\alpha}{\varphi^3} \right)^{\frac{2}{\varphi+1}} \right)^{\frac{\varphi+1}{2}} \leq \alpha$$

by inequality (45). This way, we can bound the probability of a type I error after opening and closing below a given statistical significance. As can be seen in figure 10, this approach still keeps the proportion of type I errors after opening and closing below the given statistical significance, while it decreases the number of type II errors for higher values of σ . This allows the proportion of type II errors after opening and closing to be lower than that of binarization up to $\sigma = 78$.

6 Conclusion

Theorems 4.1 and 4.2 give us a better understanding of the effects of morphological opening and closing on the error probabilities, when testing for a region of interest. The results were obtained by exploiting the prior knowledge of some properties of the region of interest. Namely, we used the fact, the the region of interest is rectangular and has a checkerboard pattern.

Especially the exponent $\frac{\varphi+1}{2}$ in inequality (44) is of high interest. For a background pixel to be falsely identified as foreground after opening, at least $\frac{\varphi+1}{2}$ many pixels background pixels have to be falsely categorized by the binarization through the statistical test. This is the *minimum number of independent points in a structuring element* that can lead to a false categorization of a pixel. With this connection in mind, the techniques to prove the main results of this paper might present themselves useful in other cases as well.

It is also important to note, that the main results only considered the categorization of a single pixel. Since we perform tests for all pixels at once, the analysis of techniques from multiple testing in connection with morphological operations would be an interesting field of study to expand the results of this paper.

A Additional proofs

Theorem A.1. *Let $m, n \in \mathbb{N}$, $c \in \mathbb{R} \setminus \{0\}$ and $\Omega = \{1, \dots, m\} \times \{1, \dots, n\}$. Assume that F follows the statistical model given in (??) and let $T(i, j)$ be the test statistic as defined in (15) and $H_1(i, j)$ be the alternative hypothesis as defined in (14). Let t be a threshold, such that*

$$\mathbb{P}_V(T(i, j) \leq t) \leq \beta$$

for all $V \in \mathcal{H}_1(i, j)$. Let \mathfrak{I} be the binary image defined by

$$\mathfrak{I}(i, j) = \mathbb{1}_{\{T(i, j) \geq t\}} \quad (49)$$

for all $(i, j) \in \Omega$.

Let $\varphi \in \mathbb{N}$ be odd. Let $\Phi_\varphi = \{-\frac{\varphi-1}{2}, -\frac{\varphi-3}{2}, \dots, \frac{\varphi-3}{2}, \frac{\varphi-1}{2}\}$ and $\Psi_\varphi = \Phi_\varphi \times \Phi_\varphi$ be a structuring element. Let $(i, j) \in \Omega$ and $V \in \mathcal{H}_1(i, j)$.

Denote by $\Lambda = \{\kappa_1, \dots, \kappa_2\} \times \{\lambda_1, \dots, \lambda_2\}$ the rROI contained in V . Let $\min\{\kappa_2 - \kappa_1 + 1, \lambda_2 - \lambda_1 + 1\} \geq \varphi$. Then the following inequalities hold:

$$\mathbb{P}_V((\mathfrak{I} \circ \Psi_\varphi)(i, j) = 0) \leq \varphi^2 \beta \quad (50)$$

$$\mathbb{P}_V(((\mathfrak{I} \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 0) \leq \varphi^2 \beta \quad (51)$$

Proof. We use $\Psi_\varphi = \Phi_\varphi \times \Phi_\varphi$ and get

$$\begin{aligned} & \mathbb{P}_V(((\mathfrak{I} \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 0) \\ &= \mathbb{P}_V \left(\bigcup_{(k, l) \in \Psi_\varphi} \bigcap_{(\tilde{k}, \tilde{l}) \in \Psi_\varphi} \bigcap_{(r, s) \in \Psi_\varphi} \bigcup_{(\tilde{r}, \tilde{s}) \in \Psi_\varphi} \{\mathfrak{I}(i + k - \tilde{k} - r + \tilde{r}, j + l - \tilde{l} - s + \tilde{s}) = 0\} \right) \\ &= \mathbb{P}_V \left(\bigcup_{k, l \in \Phi_\varphi} \bigcap_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \bigcap_{r, s \in \Phi_\varphi} \bigcup_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \{\mathfrak{I}(i + k - \tilde{k} - r + \tilde{r}, j + l - \tilde{l} - s + \tilde{s}) = 0\} \right) \end{aligned}$$

Using sub-additivity we obtain

$$\mathbb{P}_V(((\mathfrak{I} \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 0)$$

$$\begin{aligned}
 &= \mathbb{P}_V \left(\bigcup_{k,l \in \Phi_\varphi} \bigcap_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \bigcap_{r,s \in \Phi_\varphi} \bigcup_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \{\mathfrak{I}(i+k-\tilde{k}-r+\tilde{r}, j+l-\tilde{l}-s+\tilde{s}) = 0\} \right) \\
 &\leq \sum_{k,l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \bigcap_{r,s \in \Phi_\varphi} \bigcup_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \{\mathfrak{I}(i+k-\tilde{k}-r+\tilde{r}, j+l-\tilde{l}-s+\tilde{s}) = 0\} \right)
 \end{aligned}$$

We can pull the two intersections together and get

$$\begin{aligned}
 &\mathbb{P}_V((\mathfrak{I} \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 0) \\
 &\leq \sum_{k,l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{\tilde{k}, \tilde{l} \in \Phi_\varphi} \bigcap_{r,s \in \Phi_\varphi} \bigcup_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \{\mathfrak{I}(i+k-\tilde{k}-r+\tilde{r}, j+l-\tilde{l}-s+\tilde{s}) = 0\} \right) \\
 &= \sum_{k,l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{\tilde{k}, \tilde{l}, r, s \in \Phi_\varphi} \bigcup_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \{\mathfrak{I}(i+k-\tilde{k}-r+\tilde{r}, j+l-\tilde{l}-s+\tilde{s}) = 0\} \right)
 \end{aligned}$$

We drop every term in the intersection besides $r-\tilde{k}, s-\tilde{l} \in \{-(\varphi-1), \varphi-1\}$.

This yields

$$\begin{aligned}
 &\mathbb{P}_V((\mathfrak{I} \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 0) \\
 &\leq \sum_{k,l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{\tilde{k}, \tilde{l}, r, s \in \Phi_\varphi} \bigcup_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \{\mathfrak{I}(i+k-\tilde{k}-r+\tilde{r}, j+l-\tilde{l}-s+\tilde{s}) = 0\} \right) \\
 &\leq \sum_{k,l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{r-\tilde{k}, s-\tilde{l} \in \{-(\varphi-1), \varphi-1\}} \bigcup_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \{\mathfrak{I}(i+k-\tilde{k}-r+\tilde{r}, j+l-\tilde{l}-s+\tilde{s}) = 0\} \right)
 \end{aligned}$$

The sets $\bigcup_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \{\mathfrak{I}(i+k-\tilde{k}-r+\tilde{r}, j+l-\tilde{l}-s+\tilde{s}) = 0\}$ are mutually independent for $r-\tilde{k}, s-\tilde{l} \in \{-(\varphi-1), \varphi-1\}$ and fixed $k, l \in \Phi_\varphi$. Thus we obtain

$$\begin{aligned}
 &\mathbb{P}_V((\mathfrak{I} \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 0) \\
 &\leq \sum_{k,l \in \Phi_\varphi} \mathbb{P}_V \left(\bigcap_{r-\tilde{k}, s-\tilde{l} \in \{-(\varphi-1), \varphi-1\}} \bigcup_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \{\mathfrak{I}(i+k-\tilde{k}-r+\tilde{r}, j+l-\tilde{l}-s+\tilde{s}) = 0\} \right)
 \end{aligned}$$

$$= \sum_{k,l \in \Phi_\varphi} \prod_{r-\tilde{k}, s-\tilde{l} \in \{-(\varphi-1), \varphi-1\}} \mathbb{P}_V \left(\bigcup_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \{\mathfrak{I}(i+k-\tilde{k}-r+\tilde{r}, j+l-\tilde{l}-s+\tilde{s}) = 0\} \right)$$

Again, by using sub-additivity, we get

$$\begin{aligned} & \mathbb{P}_V((\mathfrak{I} \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 0) \\ & \leq \sum_{k,l \in \Phi_\varphi} \prod_{r-\tilde{k}, s-\tilde{l} \in \{-(\varphi-1), \varphi-1\}} \mathbb{P}_V \left(\bigcup_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \{\mathfrak{I}(i+k-\tilde{k}-r+\tilde{r}, j+l-\tilde{l}-s+\tilde{s}) = 0\} \right) \\ & = \sum_{k,l \in \Phi_\varphi} \prod_{r-\tilde{k}, s-\tilde{l} \in \{-(\varphi-1), \varphi-1\}} \sum_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \mathbb{P}_V \left(\{\mathfrak{I}(i+k-\tilde{k}-r+\tilde{r}, j+l-\tilde{l}-s+\tilde{s}) = 0\} \right) \end{aligned}$$

Using the assumption $\mathbb{P}_V(T(i, j) \leq t) \leq \beta$ we obtain the upper bound

$$\begin{aligned} & \mathbb{P}_V((\mathfrak{I} \circ \Psi_\varphi) \bullet \Psi_\varphi)(i, j) = 0) \\ & \leq \sum_{k,l \in \Phi_\varphi} \prod_{r-\tilde{k}, s-\tilde{l} \in \{-(\varphi-1), \varphi-1\}} \sum_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \mathbb{P}_V \left(\{\mathfrak{I}(i+k-\tilde{k}-r+\tilde{r}, j+l-\tilde{l}-s+\tilde{s}) = 0\} \right) \\ & \leq \sum_{k,l \in \Phi_\varphi} \prod_{r-\tilde{k}, s-\tilde{l} \in \{-(\varphi-1), \varphi-1\}} \sum_{\tilde{r}, \tilde{s} \in \Phi_\varphi} \beta \\ & = \sum_{k,l \in \Phi_\varphi} \prod_{r-\tilde{k}, s-\tilde{l} \in \{-(\varphi-1), \varphi-1\}} \varphi^2 \beta \\ & = \sum_{k,l \in \Phi_\varphi} (\varphi^2 \beta)^4 \\ & = \varphi^2 (\varphi^2 \beta)^4 \\ & = \varphi^{10} \beta^4 \end{aligned}$$

This finishes the proof. □

(a) Proportion of type I errors after binarization, opening and closing.

(b) Proportion of type II errors after binarization, opening and closing.

Figure 9: Proportion of type I & II errors after binarization, opening and closing. For sizes 128×128 , 256×256 , 512×512 the images were randomly generated with 5 images per size. For each images 50 different noises were randomly generated. We choose $\alpha = 0.05$.

(a) Proportion of type I errors after binarization, opening and closing.

(b) Proportion of type II errors after binarization, opening and closing.

Figure 10: Proportion of type I & II errors after binarization, opening and closing. For sizes 128×128 , 256×256 , 512×512 the images were randomly generated with 5 images per size. For each images 50 different noises were randomly generated. We choose a relaxed statistical significance $\tilde{\alpha} = \left(\frac{0.05}{3^3}\right)^{\frac{2}{3+1}}$.

Figure 11: The black area is the pixels that contribute to $(\mathcal{J} \circ \Psi_\varphi) \bullet \Psi_\varphi(i, j)$. The blue squares are mutually independent. The red pixels are the pixels that we reduce the intersection in the proof to.
